Abstract

Objective - Every day librarians make decisions that impact on the provision of library products and services. To formulate good decisions librarians must be equipped with reliable and valid data. Unfortunately, many library processes generate vast quantities of unwieldy information that is ill suited for the evidence based decision-making (EBDM) practices librarians strive to employ. Librarians require tools to facilitate the translation of unmanageable facts and figures into data that can be used to support decision-making. One such tool is a rubric. Rubrics provide benefits to librarians seeking to use EBDM strategies. This study examined librarians’ abilities to use rubrics as a decision facilitation tool, explored barriers that might prevent effective rubric usage, and suggested training topics that address potential barriers.

Methods - The data for the study came from student responses to open-ended questions embedded in an online information literacy tutorial, LOBO, used by first-year students in English 101 at North Carolina State University (NCSU). Fifteen academic librarians, five instructors, and five students applied rubrics to transform students’ textual responses into quantitative data; this data was statistically analyzed for reliability and validity using Cohen’s Kappa. Participant comment sheets were also examined to reveal potential hurdles to effective rubric use.
Results - Statistical analysis revealed that a subset of participants included in this study were able to use a rubric to achieve substantially valid results. On the other hand, some participants were unable to achieve an expert level of validity and alluded to roadblocks that interfered with their ability to provide quality data using rubrics.

Conclusion - Participant feedback can be categorized into six barriers that may explain why some participants could not attain expert status: 1) difficulty understanding an outcomes-based approach, 2) tension between analytic and holistic rubric structures, 3) failure to comprehend rubric terms, 4) disagreement with rubric assumptions, 5) difficulties with data artifacts, and 6) difficulties understanding local library context and culture. Fortunately, each of these barriers can be addressed through training topics that maximize the usefulness of a rubric approach to EBDM.

Introduction

Every day librarians make decisions that impact on the provision of library products and services. To formulate good decisions librarians must be equipped with reliable and valid data. Unfortunately, many library processes generate vast quantities of unwieldy information that is ill-suited for the evidence based decision-making (EBDM) practices librarians strive to employ. Librarians require tools that facilitate the translation of unmanageable facts and figures into data that can be used to support decision-making. One such tool is a rubric.

Rubrics are “descriptive scoring schemes” used to analyze (Moskal) and judge the quality of services, products, or performances (Popham 95). In libraries, rubrics can be employed to examine and evaluate a multitude of library products and services. For example, rubrics can capture useable data about information-seeking behavior, customer service skills, marketing and outreach efforts, collection strengths, and information commons effectiveness. This article briefly reviews the benefits of using rubrics to facilitate EBDM and outlines a study in which librarians applied a rubric to capture and understand evidence of student information literacy skills—evidence that led to the improvement of a library instruction tutorial. Primarily, this article focuses on identifying difficulties librarians may encounter when using rubrics, and it recommends training topics to maximize the usefulness of a rubric approach to EBDM. Additional elements of the study, including methodology, are described in other documents and presentations (Oakleaf, “Assessing Information Literacy”; Oakleaf “Assessment of Student”).

Rubrics Defined

Rubrics are tools that describe the parts and levels of performance of a particular task, product, or service (Hafner 1509). Rubrics are often employed to judge quality (Popham 95), and they can be used across a broad range of subjects (Moskal). “Full model rubrics” are the most descriptive type of rubric. Formatted in a chart or table, full model rubrics include target indicators or “criteria” in the left column and levels of performance across the top (Callison 34). The first of two components that comprise a full model rubric is criteria. Criteria are the essential tasks or hallmarks that indicate a successful performance (Wiggins V-6:2). Performance descriptors are the second component of rubrics. Performance descriptors “spell out what is needed, with respect to each evaluative criterion . . . [for] a high rating versus a low rating” (Popham 96).
Rubrics can be described as holistic or analytic. A holistic rubric “score[s] the overall process or product as a whole, without judging the component parts separately” (Nitko 226). Holistic rubrics provide one score for a whole product or performance based on an overall impression. Analytic rubrics “divide . . . a product or performance into essential traits or dimensions so that they can be judged separately—one analyzes a product or performance for essential traits. A separate score is provided for each trait” (Arter and McTighe 18). Individual scores can be summed to form a total score from an analytic rubric (Nitko 226).

A number of information literacy rubrics exist in the library and information science literature. The following authors report the use of rubrics to assess information literacy in higher education: D’Angelo, Merz and Mark, Rockman, Emmons and Martin, Buchanan, Franks, Gauss and Kinkema, Hutchins, Kivel, Kobritz, Warmkessel, Smalley, Knight, and Choinsky, Mark, and Murphey. While authors used rubrics to evaluate artifacts of student learning in library instruction, additional research is merited. This study sought to examine the statistical reliability and validity of rubrics used by multiple raters and to investigate barriers that might limit the effective use of rubrics in library decision-making.

Benefits of Rubrics
As a tool for EBDM, rubrics offer a number of benefits. First, rubrics provide librarians the opportunity to discuss, determine, and communicate agreed upon values (Callison 36). Librarians who create rubrics must agree upon the criteria by which a library product or service will be analyzed and evaluated. They must also come to consensus about what the different performance levels of each criterion “look like.” Through the rubric development process, librarians engage in meaningful discussions that result in shared views of the library product or service under scrutiny. Librarians who use existing rubrics as tools for EBDM can obtain similar benefits by engaging in activities and discussions to adapt a rubric to local needs. Once created or adapted, rubrics not only represent consensus views of librarians, they also communicate shared values to others, including new librarians and external stakeholders (Stevens and Levi 23). Finally, they help “combat . . . accusations that evaluators do not know what they are looking for” (Bresciani, Zelna, and Anderson 30).

Rubrics offer a second important benefit for EBDM: descriptive, yet easily digestible data (Bresciani, Zelna, and Anderson 30). Because full model rubrics include descriptions of the key components of a library product or service at a number of performance levels, they provide detailed information for decision-making. At the same time, rubric data is easily simplified. For example, one might report that a library service operated at a “good” level during 80% of observed performances. If more detail is required, the rubric definition of “good” can be added to the percentage to make it more meaningful. In this way, rubric data can be reported in simple percentages or with details described in the rubric as the situation and audience require.

Rubrics offer librarians engaged in EBDM a third significant benefit. Because rubrics analyze agreed upon, detailed descriptions of library activities, they prevent inaccuracy of scoring (Popham 95) and bias (Bresciani, Zelna, and Anderson 31). Rubrics clarify schemes for evaluation ahead of time, and therefore reduce subjectivity (Moskal).

Since rubrics guide librarians to focus on essential criteria (Callison 35), they can assess products and services more easily and objectively (Bernier 25). Even in team or collaborative environments, rubric
evaluations are “likely to be reasonably objective and consistent” (Callison 35).

Rubrics offer a fourth benefit. When rubrics are employed to make evidence based decisions about library instructional programs, as in the study described below, students are significantly impacted. Because rubrics reveal the expectations of instructors and librarians, students can focus on achieving, rather than deciphering, learning goals. Because full model rubrics offer both numerical scores and descriptions of performance levels, ratings are more meaningful to students than letter or numerical scores alone (Bresciani, Zelna, and Anderson 35). They also provide students with feedback about what they have already learned and what they have yet to learn. As a result, rubrics support student learning, self-evaluation, and metacognition.

Methodology
This study investigated librarians’ use of rubrics as an EBDM tool to improve an online information literacy tutorial. The data for the study came from student responses to open-ended questions embedded in an online information literacy tutorial, LOBO, used by first-year students in English 101 at North Carolina State University (NCSU), Raleigh, North Carolina. This study focused on one open-ended tutorial question that required students to analyze and evaluate the authority of a Web-site they intended to use as support for an academic paper.

Study participants applied a full-model, analytic rubric (Figure 1) to transform students’ textual responses into quantitative data. They then completed an open-ended comment sheet designed to capture their opinions of the process. To replicate conditions encountered in real life, the
internal (NCSU) participants in this study took part in a training session. In contrast, the external (non-NCSU) participants were provided with a substantial amount of background material, directions, and examples to familiarize them with the campus culture and study context—content that might be found in an article or written report, but they did not receive face-to-face training.

After both groups applied the rubric to the student responses, the data was statistically analyzed for reliability and validity. Data that was determined to be reliable (consistent) and valid (accurate) was put to use for instructional decision-making. Data that was not found to be both reliable and valid was further analyzed to identify barriers that impede librarians’ successful use of rubrics.

**Study Participants**

There were twenty-five participants in this study evenly divided into five groups:

- NCSU librarians
- NCSU English 101 instructors
- NCSU English 101 students
- Association of Research Libraries (ARL) instruction librarians
- ARL reference librarians with limited instruction responsibilities.

Selected participants represented a cross section in gender, race, and areas of expertise.

The fifteen internal (NCSU) participants (librarians, instructors, and students) took part in a rubric training session. Because most of the participants had little prior experience with rubrics, the researcher introduced rubrics by providing a definition, describing the component parts of rubrics, and providing the study rubric. The researcher followed a multi-step process to familiarize the participants with the task of scoring student responses. The researcher began by sharing five “anchor” responses to demonstrate the range of student responses with the participants and to model the scoring process by “thinking aloud.” Working in small groups the participants scored five more anchor responses independently and discussed the scores they assigned. During these sessions discussion groups focused on inconsistent scores and attempted to reconcile them. Following the discussion session, groups reported their scores to the full group, and the full group discussed the remaining inconsistencies and reconciled them. This process was repeated twice. Afterwards, participants scored seventy-five student responses. Finally, they completed an open-ended comment sheet and exited the scoring session.

The ten external (non-NCSU) participants did not experience a training session. Instead, they were supplied with study materials, background information, and directions delivered via the mail. The mailing included study background material, the seventy-five study responses, and the open-ended comment sheet. The participants returned their completed study materials by mail.

**Statistical Analysis**

To prepare the materials for statistical analysis, the researcher assigned each cell of the study rubric a point value. The point values were subjected to quantitative analysis to describe student performance, test for interrater reliability, and explore the validity of participants’ rubric use. Of the three statistical analyses, the last is most significant for demonstrating the utility of rubrics as tools for EBDM.

To establish that rubrics can produce valid analysis and evaluation of library products and services, this study used Cohen’s Kappa statistic and a “gold standard” approach.

**Figure 3.** Rank Order of Participants by Average Kappa

Typically used as a measurement of intrater reliability, Cohen’s Kappa can also be used to compare a group of raters to a “gold standard” to check for validity (Gwet 202). Gwet explains that the gold standard is the “correct classification of subjects made
by an experienced observer” (202). When a
gold standard approach is used, it is
assumed that “the researcher knows the
‘correct classification’ that may be due to an
expert judgment” (223). Gwet explains,
“The question that the researcher wants to
answer is whether the . . . raters agree with
the standard. Instead of evaluating the
extent of agreement between raters, the
researcher wants to know the truthfulness of
the observers’ ratings.” This approach is
also known as a “rater-to-standard
reliability” or “rater-to-expert reliability”
(223). Using Cohen’s Kappa, this study
compared each participant’s rubric scores to
the gold standard set by the researcher.
Then participants were ranked according to
their rater-to-standard reliability. For
EBDM, only scores from the most “expert”
or valid rubric users are fit for use.

A major benefit of this method for
establishing valid rubric data is that Cohen’s
Kappa statistic can be easily interpreted
using an index (Figure 2) established by
Landis and Koch (Landis and Koch 165). In
this study, Kappas were calculated for each
participant on the four rubric criteria as well
as the summary score assigned to student
responses (Figure 3).

**Expert Rubric Users**

Statistical analysis revealed that a subset of
participants included in this study were able
to achieve substantially valid results. The
top five participants—two internal (NCSU)
librarians and three instructors—formed an
expert group of raters. The expert
participants’ rubric data contributed to
improved online instruction and allowed for
comparative statistical analysis with the
other participant five-member sub-groups.
The emergence of an expert participant
group is a promising sign for the use of
rubrics to support EBDM.

On the other hand, three internal librarians
and all of the external librarians included in

the study were unable to achieve an expert
level of validity (Figure 3). An analysis of
the interrater reliability among the expert
participants (Figure 4) and non-expert
participants (Figure 5) demonstrates the
distinction between the two groups. Expert
participants demonstrated moderate and
substantial agreement across all criteria of
the study rubric as well as the overall
“grade” assigned to the student
performance. Non-expert participants
showed only fair or slight agreement across
nearly all areas of the rubric. The
application of two-sided t tests (alpha level
of .05) to this data shows that these
differences in reliability levels are
statistically significant; t values of
individual rubric criteria range from 4.2 to
16.3.

This statistical analysis revealed two
additional items worth noting. First, and
perhaps not surprisingly, the external
librarians provided the least valid rubric
results of all participants. This may be
attributable to their lack of training or lack
of familiarity with NCSU library contexts.
The second remarkable result is the wide
variation of the internal librarians’ validity
rankings. Although the highest validity
rank was achieved by a NCSU librarian, a
second NCSU librarian earned scores that
were no more accurate than external
librarians. This extreme variation across
NCSU librarians demonstrates that training
and familiarity with library culture are not
enough to ensure valid rubric usage. This
finding also highlights the importance of
conducting basic statistical tests to confirm
the validity of data used to make decisions
regarding library products and services.

**Not All Rubric Users Are Experts**

One of the most important findings of this
study is that not all rubric users are experts.
While this might seem obvious, in practice
many rubrics are used by people who have
not been verified as expert in the use of such tools. Often, expert ability is assumed based on an individual’s educational background, experience, or position in an educational institution. However, in this study the group of expert participants crossed divisions of background, experience, and institutional position. Thus, the belief that rubrics can be used reliably and validly by those who have a particular
degree, a specific type of experience, or a certain position within the institution is a faulty assumption. If rubric users are selected because of their education, experience, or position, rather than demonstrated ability to provide reliable and valid scores, library processes may be evaluated inconsistently, inaccurately, or unfairly. This study supports the idea that only the rubric results of demonstrated experts should be used to make decisions that impact library products and services.

**Characteristics of Expert Rubric Users**
While this study offers a statistical process for identifying expert rubric users, it is also wise to consider the factors that make an “expert” an expert. Why do some rubric users achieve expert status while others do not? Some possible answers to this question emerge both from the literature and from the comments of the participants in this study.

Some rubric users might be naturally proficient scorers. Wolfe, Kao, and Ranney note that the most proficient scorers tend to focus on the general features of a product or performance and “adopt values espoused by the scoring rubric” more so than less proficient scorers. Throughout the scoring process, proficient rubric users revisit the established criteria in order to ensure that consistency is maintained (Moskal). However, less proficient rubric users tend to interrupt their observation of a product or performance to monitor how well it satisfies the rubric, rather than focusing on the product or performance and then reviewing it against the rubric (Wolfe, Kao, and Ranney). The literature also reports that non-expert rubric users may have diverse outlooks, perspectives, and experiences that need to be taken into account (Colton et al. 9). Tired rubric users may not score students evenly over a time period. The mood of the rater can affect scores, as can prior knowledge (Moskal). Finally, training can impact the proficiency of rubric users, and this is born out by the significant differences between internal and external participants in this study.

In addition, there may be other barriers that keep rubric users from becoming experts. In this study, participants completed an open-ended comment sheet after scoring student responses. Non-expert participants alluded to some of these roadblocks in their comments. Their comments can be categorized into six barriers that may explain why some participants could not attain expert status.

**Barrier 1: Difficulty Understanding an Outcomes-Based Approach**
Libraries have a strong tradition of using input and output measures to evaluate products and services, and sometimes they are slow to adopt outcomes-based approaches. As a result, librarians may struggle with outcomes-based tools such as rubrics. The rubric used in this study was based on outcomes included in the Association of College and Research Libraries’ *Information Literacy Competency Standards for Higher Education*, a document well known among academic reference and instruction librarians. Despite the popularity of these standards and the recent push for outcomes-based assessment of information literacy skills in academic libraries, some participants of the study appeared to be unfamiliar with key concepts of outcomes-based methods. A few participants voiced concerns that an outcomes-based approach to the assessment of information literacy instruction may fail to measure what they termed student “understanding” or “ability.” These participants felt that using measurable outcomes to assess student learning focused too much on specific skills—too much “science” and not enough “art.” One participant wrote, “While the rubric measures the presence of concepts . . . , it
doesn’t check to see if students understand [the issues].” Another participant stated, “This rubric tests skills, not . . . real learning.” These comments indicate that librarians need to learn more about the values and principles of outcomes-based assessment before they can make meaningful progress in the assessment of information literacy skills.

The need for improvement in this area has also been noted in the literature. Despite reports that librarians are increasingly asked to join other educators in justifying their programs using learning outcomes (Lichtenstein 28), Iannuzzi reports, “We have yet to see widespread implementation of outcomes assessment methodologies in terms of student learning in our academic libraries” (Iannuzzi 304). Despite the slow diffusion of such measures, outcomes-based approaches offer real benefits to librarians striving to use EBDM practices to advance library programs. Smith states, “It is important for libraries to understand the processes that are used to define learning outcomes, to select measures, to collaborate with other academic departments, and to use the results to improve their programs.”

**Barrier 2: Tension Between Analytic and Holistic Approaches**

A second barrier that may have prevented some librarians in this study from attaining expert status is a lack of comfort with analytical evaluation. One participant worried that parsing user behavior into components may result in oversimplification, commenting that using the rubric “was really simple. But I worried that I was being too simplistic . . . and not rating [student work] holistically.” Another participant seemed to prefer assigning an “overall” score, stating “the rubric is a good and a solid way to measure knowledge of a process, but it does not allow for raters to assess the response as a whole.”

These comments reveal tension between analytic and holistic approaches to evaluation. Both approaches have advantages and disadvantages. Arter and McTighe recommend holistic rubrics for simple products or performances, particularly ones with only one important criterion to assess. They also note that holistic rubrics are useful for “getting a quick snapshot of overall quality or achievement” (Arter and McTighe 21). Unfortunately, holistic rubrics provide only limited feedback (Mertler) and provide “no detailed analysis of the strengths and weaknesses of a product or performance. So, they’re not as useful diagnostically to help plan instruction. Nor do they provide students with detailed feedback to guide their improvement” (Arter and McTighe 21).

Because analytic rubrics “divide . . . a product or performance into essential traits or dimensions so that they can be judged separately” (Arter and McTighe 18), they allow for separate evaluations of each factor along a different descriptive scale (Moskal). This part-to-whole approach makes analytic rubrics better suited for “judging complex performances (e.g., research process) involving several significant dimensions” (Arter and McTighe 22). According to Mertler, analytic rubrics are preferred when a focused response to stakeholders is required. However, these advantages come at a cost. Analytical rubrics take more time to create and to use. Arter and McTighe write, “After all, you have more to discern” (23).

The decision to use a holistic or analytic rubric is one that should be based on the product or performance to be assessed, the criteria to be observed, and the purpose of the assessment. Mertler states that the most important factor to consider is how the results of the assessment will be used. He writes, “If an overall, summative score is desired, a holistic scoring process would be
more desirable. In contrast, if formative feedback is the goal, an analytic scoring rubric should be used.” In the case of the study rubric, formative feedback was required, not only for students, but also for librarians. Without formative feedback, librarians could not make decisions for improvements to the tutorial. In a different EBDM scenario, a holistic rubric might be more appropriate.

**Barrier 3: Failure to Comprehend the Rubric**

A third issue that may prevent rubric users from becoming “experts” is simple: a failure to understand some aspect of the rubric. Nearly all the participants used in this study claimed that they understood the terms used in the rubric. Still, one important comprehension problem surfaced during this study. A few external librarian participants failed to realize that rubrics are intended to judge performances on quality, not quantity, or how many times a performance is observed (Callison 36). One participant wrote, “The student might cite one example, . . . but not . . . enough for me to consider it exemplary.” This focus on quantity rather than quality reveals a lack of experience with rubric design that might be easily addressed through training.

**Barrier 4: Disagreement with Assumptions of the Rubric**

The content of any rubric is based on certain assumptions. In this study, the major assumption is that the capacity to use the criterion of authority for Web site evaluation is comprised of the ability to use criterion terminology, cite examples of indicators of the criterion, identify those indicators in an example Web site, and make a reasoned decision about the use of the example Web site. This assumption is based on two documents from the Association of College and Research Libraries: the Information Literacy Competency Standards for Higher Education and the Objectives for Information Literacy Instruction: A Model Statement for Academic Librarians. Perhaps the biggest hurdle for some study participants was their disagreement with the standards on which the rubric was based; as a result, they could not fully internalize the assumptions of the rubric. The standard that posed the most difficulty for participants was Standard 3.2, which reads, “The information literate student articulates and applies initial criteria for evaluating both the information and its sources.” Several participants argued that students should not have to articulate Web evaluation criteria—in this case, authority. These participants felt that assessing students’ ability to use criteria terminology resulted in “looking for specific terms and missing the overall point of the responses.” One participant commented that by expecting students to articulate criteria terminology, the rubric “valued students’ ability to use particular words but does not measure their understanding of concepts.” This comment indicates that disagreement with one part of the rubric impacted the participant’s ability to adopt the rubric in its entirety.

It is important to note that conflicts with the assumptions of a rubric might be avoided if participants are included in the rubric development process. For this study, such an approach was not feasible, but research confirms the value of allowing stakeholders to discuss and determine agreed upon values of student learning.

**Barrier 5: Difficulties with Artifacts**

Artifacts of library processes present a fifth potential barrier to participants’ expert status. In this study, several participants commented on the difficulty of interpreting artifacts of student learning because some student responses were cryptic, incomplete, vague, or incorrect. One external participant said that she found herself “giving the more cryptic answers the benefit of the doubt.” Another complained that
student responses were sometimes incomplete. She questioned, “If a student answer consists of a bulleted list of responses to the prompt, but no discussion or elaboration, does that fulfill the requirement?” Another lamented, “It’s really hard . . . . when students are asked to describe, explain, draw conclusions, etc. and some answer with one word.” A fourth asked, “Should the rubric be used on ‘text’ that isn’t in complete sentence form? How much should one use the LOBO prompt to interpret student answers?” Some participants were stymied by incorrect or partially incorrect answers. One wrote, “I suspect my own perceptions of the ‘correctness’ of the answers affected me.” Another stated, “It killed me that I couldn’t take points off for incorrect information.” These comments indicate that difficulties with artifacts can affect participants’ ability to produce reliable (consistent) and valid (accurate) results.

Barrier 6: Difficulties Understanding Library Context and Culture

In this study, external librarian participants achieved the lowest levels of validity, a result that could be due to lack of training or a lack of familiarity with NCSU library conventions and culture. It appears that the typical model of exporting a tool that works at one library for use in another library via professional listservs or journals may not produce valid data for EBDM. This is an important finding with implications for librarians’ professional practice. If tools are to be shared among libraries, perhaps local training and adaptation are necessary, and the results should be statistically analyzed to confirm data quality.

The Need for Training

In the hands of experts, the rubrics employed in this study yielded detailed and comprehensible data that facilitated instructional decision-making. This study also reveals that non-expert rubric users may be unable to produce valid evaluations of library products and services without additional local training.

To overcome barriers to successful rubric usage, training should teach librarians the value and principles of outcomes-based approaches to library analysis and evaluation. Training should incorporate the theories that underlie rubrics as well as the advantages and disadvantages of analytic and holistic rubric models. In addition, training should cover the structural issues that can limit the reliability, validity, and overall usefulness of rubrics: some rubrics are not well written (Popham 95); some use wording that is too general or too specific (Tierney and Simon); some are too long (Popham 98); some include inconsistencies (Tierney and Simon); and some emphasize quantity rather than quality (Callison 36). Furthermore, training should address methods for eliminating disagreement with assumptions of a rubric. Finally, because rubrics may be used to analyze and evaluate library products and services that generate “messy” data, training should review the difficulties librarians are likely to encounter in the data and methods for handling them.

Conclusion

This study demonstrated that not all librarians are proficient or “expert” in the use of rubrics. It also revealed that six barriers may impact librarians’ ability to apply rubrics for EBDM: 1) difficulty understanding outcomes-based assessment; 2) tension between analytic and holistic rubric approaches; 3) failure to comprehend rubric content; 4) disagreement with rubric assumptions; 5) difficulties with artifacts of library processes; and 6) difficulty understanding non-local library context and culture. All these barriers can be addressed by training. However, if training is required to help librarians use rubrics to produce reliable and valid results, skeptics might ask if the benefits are worth the time and energy
required. Certainly, there are costs associated with training, but the advantages of rubrics outweigh the costs (Prus and Johnson 25). The participants of this study confirmed the value of rubrics—nearly all participants stated that they could envision using rubrics to improve library instructional services. Indeed, results from the study were used to enhance tutorial content and questions. Both participant feedback and tutorial improvements attest to the merit of rubrics as tools for effective EBDM practice. Future research efforts should focus on the attributes of expert raters and the effects of different types and levels of rater training; these research foci will illuminate best practices in the use of rubrics for EBDM. In short, librarians eager to use EBDM strategies should invest in rubric training and pursue research in this area. To do otherwise is to discard a viable approach to EBDM that offers librarians a wealth of benefits.
