On Testing for Sphericity with Non-normality in a Fixed Effects Panel Data Model

Badi H. Baltagi*, Chihwa Kao**, Bin Peng

Abstract

Building upon the work of Chen et al. (2010), this paper proposes a test for sphericity of the variance-covariance matrix in a fixed effects panel data regression model without the normality assumption on the disturbances.

Keywords: Sphericity; Panel Data; Cross-sectional Dependence; John Test.

JEL Classification: C13; C33.

1. Introduction

This paper proposes testing the null of sphericity of the variance-covariance matrix in a fixed effects panel data model which does not require the normality assumption on the disturbances. This builds on the paper by Chen et al. (2010) who use $U$-statistics to test for sphericity of the variance-covariance matrix in statistics. The null of sphericity means that the variance-covariance matrix is proportional to the identity matrix. Rejecting the null means having cross-sectional dependence among the individual units of observation or heteroskedasticity or both. In empirical economic studies, individuals are affected by common shocks. For example, investors’ decisions may be influenced by the way they interact with each other and also by common macro-economic shocks or public policies. These potentially cause cross-sectional dependence among the units.

Preprint submitted to Elsevier December 15, 2014
In statistics, the $n \times n$ sample covariance matrix $S_n$ is widely used for tests of sphericity since it is a consistent estimator for the variance-covariance matrix $\Sigma_n$. One could either use the likelihood ratio test, see [Anderson (2003)], or test the Frobenius norm of the difference between $S_n$ and $\Sigma_n$, see [John (1971, 1972)]. However, with panel data sets where $n$ the number of individuals is larger than the time series dimension of the data $T$, the sample covariance matrix becomes singular. This causes problems for the likelihood ratio test which is based on the inverse of $S_n$. Even when $n$ is smaller than $T$, the sample covariance matrix $S_n$ is ill-conditioned as shown in the Random Matrix Theory (RMT) literature. In fact, the eigenvalues of the sample covariance matrix $S_n$ are no longer consistent for their population counterpart, see [Johnstone (2001)]. Ledoit and Wolf (2004) show that the scaled Frobenius norm of $S_n$ does not converge to that of $\Sigma_n$ with $n/T \to c \in (0, \infty)$. As a result, John’s test, see [John (1971, 1972)], is no longer applicable. Hence, Ledoit and Wolf (2002) propose a new test for the null of sphericity which could be applied even when $n$ is relatively as large as $T$. However, these statistical tests for raw data are not directly applicable to testing sphericity in panel data regressions since the disturbances are unobservable. Baltagi et al. (2011) extend the Ledoit and Wolf (2002)’s John test to the fixed effects panel data model and correct for the bias due to substituting within residuals for the actual disturbances. However, their test relies on the normality assumption and their simulation results show that the test has size distortion under non-normality of the disturbances.

To account for the possible “non-normality” of the disturbances as well as the “large $n$, small $T$” issues in testing the null of sphericity, Chen et al. (2010) propose a modified John test by constructing $U$-statistics of observable samples for estimating $\text{tr}\Sigma_n$ and $\text{tr}\Sigma^2_n$. Based on their work, this paper proposes a new test for the null of sphericity of the disturbances in a fixed effects regression panel data model. This test does not require the assumption of normality of the disturbances, and can be applied to the case where $n$ is larger than $T$. The limiting distribution of this test statistic under the null is derived. Also, its finite sample properties are studied using Monte Carlo simulations.

The paper is organized as follows. Section 2 specifies the fixed effects panel data regression model and the assumptions required. Section 3 introduces the test statistic. Section 4 derives the limiting distribution of this test statistic under the null and discusses its power properties. Section 5 reports the results of Monte Carlo simulations, while Section 6 concludes. All the proofs and technical details can be found in an Appendix available upon request from the authors.
Notation: \(|B| = (\text{tr}(B'B))^{1/2}\) is the Frobenius norm of a matrix \(B\) or the Euclidean norm of a vector \(B\), and \(\text{tr}(B)\) is the trace of \(B\). \(\xrightarrow{d}\) denotes convergence in distribution and \(\xrightarrow{p}\) denotes convergence in probability. For two matrices \(B = (b_{ij})\) and \(C = (c_{ij})\), we define \(B \circ C = (b_{ij}c_{ij})\).

2. The Model and Assumptions

Consider the following fixed effects panel data regression model

\[
y_{it} = \alpha + x'_{it}\beta + \mu_i + v_{it}, \text{ for } i = 1, 2, \ldots, n; \quad t = 1, 2, \ldots, T, \tag{2.1}
\]

where \(i\) indexes the cross-sectional dimension and \(t\) indexes the time series dimension. \(y_{it}\) is the dependent variable, \(x_{it}\) denotes the \(k \times 1\) vector of exogenous regressors, and \(\beta\) is the corresponding \(k \times 1\) vector of parameters. \(\mu_i\) denotes the time-invariant individual effects which can be fixed or random and could be correlated with the regressors. Define the vector of disturbances \(v_t = (v_{1t}, \ldots, v_{nt})'\) and its corresponding variance-covariance matrix \(\Sigma_n\). The null hypothesis of interest is sphericity:

\[
H_0 : \Sigma_n = \sigma^2_n I_n \quad \text{vs} \quad H_1 : \Sigma_n \neq \sigma^2_n I_n. \tag{2.2}
\]

The alternative hypothesis allows cross-sectional dependence or heteroskedasticity or both.

For the panel data regression model, \(v_{it}\) is unobserved, and the test statistic is based upon consistent estimates of variance-covariance matrix, denoted by \(S_n\) or its correlation coefficients matrix counterpart, see Breusch and Pagan (1980). Baltagi et al. (2011) extend the Ledoit and Wolf (2002) test to a fixed effects panel data model with large \(n\) and large \(T\). They show that the noise resulting from using within residuals rather than the actual disturbances accumulates and causes bias for the proposed test statistic. However, their simulations show that their test is oversized under non-normality of the disturbances. This paper extends Chen et al. (2010) to test the null of sphericity of the variance-covariance matrix of the disturbances in a fixed effects panel data regression model without assuming normality of the disturbances. We use the within residuals which are given by

\[
\hat{v}_{it} = \hat{y}_{it} - \hat{x}'_{it}\hat{\beta} = v_{it} - \bar{v}_i - \bar{x}'_{it}\left(\hat{\beta} - \beta\right), \tag{2.3}
\]

where \(\bar{x}_{it} = x_{it} - \bar{x}_i\) and \(\bar{v}_i = \frac{1}{T} \sum_{t=1}^{T} x_{it}\). Similarly, \(\bar{y}_{it} = y_{it} - \bar{y}_i\), \(\bar{y}_i = \frac{1}{T} \sum_{t=1}^{T} y_{it}\), and \(\bar{v}_i = \frac{1}{T} \sum_{t=1}^{T} v_{it}\). The within estimator of \(\beta\) is given by \(\hat{\beta} = \left(\sum_{t=1}^{T} \sum_{i=1}^{n} \bar{x}_{it} \bar{x}'_{it}\right)^{-1} \left(\sum_{t=1}^{T} \sum_{i=1}^{n} \bar{x}_{it} \bar{y}_{it}\right)\).
Let \( \tilde{y}_t = (\tilde{y}_{1t}, \ldots, \tilde{y}_{nt})' \), \( \tilde{v}_t = (\tilde{v}_{1t}, \ldots, \tilde{v}_{nt})' \), \( \tilde{\varepsilon}_t = (\tilde{\varepsilon}_1, \ldots, \tilde{\varepsilon}_n)' \), and \( \tilde{x}_t = (\tilde{x}_{1t}, \ldots, \tilde{x}_{nt}) \). The within residuals can be rewritten in matrix form as \( \tilde{v}_t = v_t - \bar{v} - \tilde{x}_t' \left( \tilde{\beta} - \hat{\beta} \right) \). To facilitate our analysis, we require the following assumptions:

**Assumption 1.** The \( n \times 1 \) vectors \( v_1, v_2, \ldots, v_T \) are independent and identically distributed (i.i.d.) with mean vector 0 and covariance matrix \( \Sigma_n = \Gamma \Gamma' \), where \( \Gamma \) is an \( n \times m \) \( (m \leq \infty) \) matrix, \( v_t \) can be written as \( v_t = \Gamma Z_t \), where \( Z_t = (z_{t1}, \ldots, z_{tm}) \) are i.i.d. random vectors with mean vector 0 and covariance matrix \( I_m \). We also assume that each \( v_{it} \), for \( i = 1, \ldots, n \) has uniformly bounded 8th moment and there exists a finite constant \( \Delta \) such that \( E(z_{it}^8) = 3 + \Delta \), for \( l = 1, \ldots, m \).

**Assumption 2.** The regressors \( x_{it} \), \( i = 1, \ldots, n \), \( t = 1, \ldots, T \) are independent of the idiosyncratic disturbances \( v_{it} \), \( i = 1, \ldots, n \), \( t = 1, \ldots, T \). The regressors \( x_{it} \) have finite fourth moments: \( E(||x_{it}||^4) \leq K < \infty \), where \( K \) is a positive constant.

**Assumption 3.** As \( (n, T) \to \infty \), \( \text{tr}(\Sigma_n^2) \to \infty \), \( \text{tr}(\Sigma_n^4)/\text{tr}^2(\Sigma_n^2) \to 0 \).

The asymptotics follow the framework employed by Chen et al. (2010). Assumption 3 requires \( \text{tr}(\Sigma_n^4) \) to grow at a slower rate than \( \text{tr}^2(\Sigma_n^2) \). This assumption is flexible. In fact, if all the eigenvalues of \( \Sigma_n \) are bounded away from zero and infinity, \( \text{tr}(\Sigma_n^4)/\text{tr}^2(\Sigma_n^2) \to 0 \), is always true for any \( n \) as \( n \to \infty \). Moreover, this assumption allows \( n \) to be much larger than \( T \), which is more suitable for micro-panel data.

### 3. J_n Test

For testing the null hypothesis (2.2), the test statistic is based on the scaled distance measure between \( \sigma_v^{-2} \Sigma_n \) and \( I_n \):

\[
U_0 = \frac{1}{n} \text{tr} \left[ S_n \left( \frac{1}{n} \text{tr} S_n \right)^{-1} - I_n \right]^2 = \left( \frac{1}{n} \text{tr} S_n \right)^{-2} \left( \frac{1}{n} \text{tr} (S_n^2) \right) - 1,
\]

where \( S_n \) is the \( n \times n \) sample covariance matrix and \( I_n \) is an \( n \times n \) identity matrix. With the normality assumption, John (1972) shows that for fixed \( n \), and as \( T \to \infty \):

\[
\frac{nT}{2} U_0 \overset{d}{\to} \chi_{n(n+1)/2-1}^2.
\]
But when \( n \) goes to infinity, the test statistic diverges. Ledoit and Wolf (2002) propose a modified test statistic under the null, as \((n, T) \to \infty\) and \(n/T \to c \in (0, \infty)\):

\[
TU_0 - n \xrightarrow{d} N(1, 4). \tag{3.3}
\]

Define \( J_0 = \frac{TU_0 - n}{2} - \frac{1}{2} \), then under the null \( J_0 \xrightarrow{d} N(0, 1) \). However, this test cannot be used directly in a fixed effects panel data regression model. The raw data sample covariance matrix \( S_n \) is replaced by its counterpart \( \hat{S}_n \) which is the within residual given by (2.3). The residual-based \( \hat{U}_0 \) is defined as 

\[
\hat{U}_0 = \left( \frac{1}{n} \text{tr} \hat{S}_n \right)^{-2} \frac{1}{n} \text{tr} \left( \hat{S}_n^2 \right) - 1 \quad \text{and the corresponding residual-based } J_0 \text{ test is } \hat{J}_0 = \frac{T \hat{U}_0 - n}{2} - \frac{1}{2}. \text{ Baltagi et al. (2011) propose a bias correction:}
\]

\[
J_{BFK} = \hat{J}_0 - \frac{n}{2(T - 1)}. \tag{3.4}
\]

They show that in a fixed effects panel data regression, as \((n, T) \to \infty\) and \(n/T \to c \), \( J_{BFK} \xrightarrow{d} N(0, 1) \) under the null. However, their result relies on the normality assumption of \( v_t \). Without the normality assumption, the bias-corrected John test is not robust, see the simulations in Baltagi et al. (2011).

Chen et al. (2010) propose a new test statistic for the sphericity of the variance-covariance matrix of the disturbances without the normality assumption and under much relaxed conditions where \( n \) could be much larger than \( T \). They construct the \( U \)-statistics for estimating \( \text{tr} \Sigma_n \) and \( \text{tr} \Sigma_n^2 \). Following their framework, we propose a residual-based test statistic for testing the null of sphericity described in (2.2) in a fixed effects panel data model. Define

\[
\hat{M}_{1,T} = \frac{1}{T} \sum_{t=1}^{T} \hat{v}_t^t \hat{v}_t; \quad \hat{M}_{2,T} = \frac{1}{C^2_T} \sum_{t \neq s}^{T} \sum_{s=1}^{T} \hat{v}_t^t \hat{v}_s; \quad \hat{M}_{3,T} = \frac{1}{C^3_T} \sum_{t \neq s \neq r}^{T} \sum_{r=1}^{T} (\hat{v}_t^t \hat{v}_s) \hat{v}_r; \quad \hat{M}_{4,T} = \frac{1}{C^4_T} \sum_{t \neq s \neq r \neq \tau}^{T} \sum_{\tau=1}^{T} \hat{v}_t^t \hat{v}_s \hat{v}_r \hat{v}_\tau; \quad \hat{M}_{5,T} = \frac{1}{C^5_T} \sum_{t \neq s \neq r \neq \tau \neq \eta}^{T} \sum_{\eta=1}^{T} \hat{v}_t^t \hat{v}_s \hat{v}_r \hat{v}_\tau \hat{v}_\eta,
\]

where \( C^i_T = T!/(T - i)! \). Also, let \( \hat{R}_1 = \hat{M}_{1,T} - \hat{M}_{2,T} \) and \( \hat{R}_2 = \hat{M}_{3,T} - 2\hat{M}_{4,T} + \hat{M}_{5,T} \). If we observe the true \( v_t \), then \( R_1, R_2 \) and \( M_{j,T} \), for \( j = 1, 2, 3, 4, 5 \) are obtained similarly by replacing \((\hat{v}_t, \hat{v}_s, \hat{v}_r, \hat{v}_\eta)\) with \((v_t, v_s, v_r, v_\eta)\). \( R_1 \) and \( R_2 \) are unbiased estimators for \( \text{tr} \Sigma_n \) and \( \text{tr} \Sigma_n^2 \), respectively. The scaled distance measure between \( \sigma_v^{-2} \Sigma_n \) and \( I_n \) is given by \( U_T = \frac{n \hat{R}_2}{R_1^2} - 1 \). Define

\[
U_T = \frac{n \hat{R}_2}{R_1^2} - 1.
\]
A = \Gamma'\Gamma and \psi^2 = \frac{4}{T^2} + \frac{8}{T} \text{tr} \left[ \left( \frac{\Sigma_n}{\text{tr}(\Sigma_n)} \right)^2 \right] + \frac{44}{T} \text{tr} \left[ \left( \frac{A^2}{\text{tr}(\Sigma_n)} - \frac{A}{\text{tr}(\Sigma_n)} \right) \circ \left( \frac{A^2}{\text{tr}(\Sigma_n)} - \frac{A}{\text{tr}(\Sigma_n)} \right) \right].

Chen et al. (2010) show that as \((n, T) \rightarrow \infty:
\psi^{-1} \begin{bmatrix} \left( \frac{U_T + 1}{n} \right) \left( \frac{\text{tr}^2(\Sigma_n)}{\text{tr}(\Sigma_n^2)} \right) - 1 \end{bmatrix} \overset{d}{\rightarrow} N(0, 1).
\tag{3.5}

Let \(J_{CZZ} = \frac{T U_T}{2}\), then under the null \(J_{CZZ} \overset{d}{\rightarrow} N(0, 1)\). Following this framework, we propose the following test statistic:
\[ J_u = \frac{T}{2} U_T = \frac{T}{2} \begin{bmatrix} \hat{R}_2 - \hat{R}_1 \end{bmatrix}. \tag{3.6} \]

\(J_u\) is the residual-based statistic corresponding to \(J_{CZZ}\). There are two important issues to be considered. First, whether the residual-based \(\hat{R}_1\) and \(\hat{R}_2\) are consistent estimates for \(\text{tr} \Sigma_n\) and \(\text{tr} \Sigma_n^2\) under the null, respectively. Second, the asymptotics of the proposed test need to be derived. Both concerns are tackled in the next Section.

4. Asymptotics of the \(J_u\) Test

In this Section, we prove that, under the null, \(\frac{1}{n} \hat{R}_1\) and \(\frac{1}{n} \hat{R}_2\) are consistent estimators for \(\frac{1}{n} \text{tr} \Sigma_n = \sigma_n^2\) and \(\frac{1}{n} \text{tr} \Sigma_n^2 = \sigma_n^4\), respectively. Next, we show \(J_u\) converges to \(N(0, 1)\) under the null and we discuss its power properties. To examine the asymptotics of \(J_u\), we rewrite it as
\[ J_u = J_{CZZ} + (J_u - J_{CZZ}) = J_{CZZ} + \frac{T}{2} \left( U_T - U_T \right). \tag{4.1} \]

The first term \(J_{CZZ}\) is asymptotically standard normal under the null. The second term \(J_u - J_{CZZ}\) is the scaled difference between the residual-based \(\hat{U}_T\) and the true \(U_T\). From Section 3, this difference can be rewritten as follows:
\[ J_u - J_{CZZ} = \frac{T}{2} \begin{bmatrix} \left( \frac{1}{n} \hat{R}_2 - \frac{1}{n} R_1 \right)^2 - \left( \frac{1}{n} R_2 - \frac{1}{n} R_1 \right)^2 \end{bmatrix} \left( \frac{1}{n} \hat{R}_2 \right) - 2 \left( \frac{1}{n} R_1 \right)^{\frac{3}{2}}. \tag{4.2} \]

From equation (4.2), it is clear that this term depends upon the two differences: \(\frac{1}{n} \hat{R}_1 - \frac{1}{n} R_1\) and \(\frac{1}{n} \hat{R}_2 - \frac{1}{n} R_2\). Their asymptotic behavior is given in the following propositions:

**Proposition 1.** Under Assumptions 1-2 and the null, (1) \(\frac{1}{n} \hat{M}_{1,T} = \frac{1}{n} M_{1,T} - \frac{\sigma^2}{T} + O_p \left( \frac{1}{T^{\frac{3}{2}}} \right); \) (2) \(\frac{1}{n} \hat{M}_{2,T} = \frac{1}{n} M_{2,T} - \frac{\sigma^2}{T} + O_p \left( \frac{1}{T^{\frac{3}{2}}} \right); \) (3) \(\frac{1}{n} \hat{R}_1 - \frac{1}{n} R_1 = O_p \left( \frac{1}{T^{\frac{3}{2}}} \right). \)
Proposition 2. Under Assumptions 1-2 and the null, (1) $\frac{1}{n} \hat{M}_{3,T} = \frac{1}{n} M_{3,T} + \frac{n-2}{2T} \sigma^4_v + O_p \left( \frac{\sqrt{n}}{T} \right)$ + $O_p \left( \frac{1}{T^2} \right); \ (2) \frac{1}{n} \hat{M}_{4,T} = \frac{1}{n} M_{4,T} + \frac{n-2}{2T} \sigma^4_v + O_p \left( \frac{1}{\sqrt{n}} \right) + O_p \left( \frac{1}{T^2} \right)$; \ (3) $\frac{1}{n} \hat{M}_{5,T} = \frac{1}{n} M_{5,T} + \frac{n-2}{2T} \sigma^4_v + O_p \left( \frac{\sqrt{n}}{T^2} \right); \ (4) \frac{1}{n} \hat{R}_2 - \frac{1}{n} R_2 = O_p \left( \frac{1}{T^2} \right) + O_p \left( \frac{1}{n^2} \right) + O_p \left( \frac{1}{n^{3/2}} \right).$

Propositions 1 and 2 show that the differences $\frac{1}{n} \hat{R}_1 - \frac{1}{n} R_1$ and $\frac{1}{n} \hat{R}_2 - \frac{1}{n} R_2$ vanish as $n, T \to \infty$. Therefore, since $\frac{1}{n} R_1 \overset{p}{\to} \sigma^2_v$ and $\frac{1}{n} R_2 \overset{p}{\to} \sigma^4_v$, we conclude that $\frac{1}{n} \hat{R}_1$ and $\frac{1}{n} \hat{R}_2$ are consistent estimates for $\sigma^2_v$ and $\sigma^4_v$ respectively. The following corollary gives these conclusions:

Corollary 1. Under Assumptions 1-2 and the null, as $(n, T) \to \infty$, (1) $\frac{1}{n} \hat{R}_1 \overset{p}{\to} \sigma^2_v$; (2) $\frac{1}{n} \hat{R}_2 \overset{p}{\to} \sigma^4_v$.

Note that $\frac{1}{n} \hat{R}_2$ is a consistent estimator of $\sigma^4_v$ under the null with large $n$ and large $T$. However, $\frac{1}{n} \text{tr} S^2_n$ is not consistent, see [Baltagi et al. (2011)].

Proposition 3. Under Assumptions 1-2 and the null, $\frac{T(\tilde{U}_T - U_T)}{2} = O_p \left( \frac{1}{n} \right) + O_p \left( \frac{1}{T} \right) + O_p \left( \frac{1}{\sqrt{nT}} \right).$

Propositions 1, 2 and 3 give the asymptotics of the bias term $J_a - J_{CZZ}$. Compared with the statistic based on raw data, the test statistic based on the within residuals, defined below equation (2.3), can be expressed by $\tilde{v}_1 = v_1 - \tilde{v} - \tilde{z}_1' \left( \tilde{\beta} - \beta \right)$. This has the additional terms $\tilde{v}$ and $\tilde{z}_1' \left( \tilde{\beta} - \beta \right)$. These two terms can be regarded as extra noise resulting from the regression. Based on equations (4.1) and (4.2), the extra noise $\frac{T(\tilde{U}_T - U_T)}{2}$ depends upon $\frac{1}{n} \hat{R}_1 - \frac{1}{n} R_1 = \frac{1}{n} (\hat{M}_{1,T} - M_{1,T}) - \frac{1}{n} (\hat{M}_{2,T} - M_{2,T})$ and $\frac{1}{n} \hat{R}_2 - \frac{1}{n} R_2 = \frac{1}{n} (\hat{M}_{3,T} - M_{3,T}) - \frac{2}{n} (\hat{M}_{4,T} - M_{4,T}) + \frac{1}{n} (\hat{M}_{5,T} - M_{5,T})$. Hence the magnitude of $\frac{T(\tilde{U}_T - U_T)}{2}$ depends upon how $\tilde{v}$ and $\tilde{z}_1' (\tilde{\beta} - \beta)$ accumulate in $\left( \frac{1}{n} \hat{M}_{j,T} - \frac{1}{n} M_{j,T} \right)$, for $j = 1, 2, 3, 4, 5$. Note that $\tilde{v}$ is an $n$ dimensional vector, although each element of $\tilde{v}$ is $O_p \left( \frac{1}{\sqrt{nT}} \right)$, $\tilde{v}$ may still accumulate in the above five terms as $(n, T) \to \infty$, depending upon the relative speed of $n$ and $T$. $\tilde{z}_1' (\tilde{\beta} - \beta)$ is $O_p \left( \frac{1}{\sqrt{nT}} \right)$ which is related to both $n$ and $T$. We may expect its convergence speed $\frac{1}{\sqrt{nT}}$ to be fast enough so that $\tilde{z}_1' (\tilde{\beta} - \beta)$ vanishes as $(n, T) \to \infty$. More specifically, Proposition 2 shows the leading terms of $\frac{1}{n} \hat{M}_{j,T} - \frac{1}{n} M_{j,T}$, for $j = 3, 4, 5$ will not vanish if $nT$ does not converge to zero. These terms are caused by the accumulation of $\tilde{v}$. However, due to the subtraction formulation of the test statistic, the leading terms cancel each other in both $\frac{1}{n} \hat{R}_1 - \frac{1}{n} R_1$ and $\frac{1}{n} \hat{R}_2 - \frac{1}{n} R_2$. Similar cancellations occur for other terms which are $O_p \left( \frac{1}{\sqrt{nT}} \right)$, $O_p \left( \frac{1}{T^2} \right)$ and $O_p \left( \frac{1}{n^{3/2}} \right)$ since their expressions are exactly the same. These cancellations lead us to $\frac{1}{n} \hat{R}_1 - \frac{1}{n} R_1 = O_p \left( \frac{1}{\sqrt{nT}} \right)$ and $\frac{1}{n} \hat{R}_2 - \frac{1}{n} R_2 = O_p \left( \frac{1}{\sqrt{nT}} \right) + O_p \left( \frac{1}{n^{3/2}} \right)$, and consequently $\frac{T(\tilde{U}_T - U_T)}{2} = O_p \left( \frac{1}{n} \right) + O_p \left( \frac{1}{T} \right) + O_p \left( \frac{1}{\sqrt{nT}} \right)$. Therefore, $J_a - J_{CZZ} \overset{p}{\to} 0$ as $(n, T) \to \infty$ and we do
not need to correct the bias in the fixed effects panel data regression model. This result is based on our detailed calculation of how \( \hat{\beta} \) and \( \hat{x}'_t(\hat{\beta} - \beta) \) are accumulating in \( \left( \frac{1}{n} M_{j,T} - \frac{1}{n} M_{j,T} \right) \), for \( j = 1, 2, 3, 4, 5 \) and the special formulation of \( J_{CZZ} \). As discussed above, the convergence of \( J_u \) is given by the following theorem:

**Theorem 1.** Under Assumptions 1-3 and the null, in the fixed effects panel data regression model (2.1), as \( (n,T) \to \infty \)

\[
J_u \xrightarrow{d} N(0,1). \tag{4.3}
\]

Under the alternative, the limiting distribution of \( J_u \) is the same as (3.5) if \( T(U_{T-UT}) \) vanishes as \( (n,T) \to 0 \). Similar to Chen et al. (2010), we consider an alternative: \( H_1 : \Sigma_n = (\sigma_i \sigma_j \rho^{j-i})_{n \times n} \), where \( \rho \in (-1,1) \) and \( \rho \neq 0 \). \( \sigma_i^2 = \text{var}(v_{it}) \), which is uniformly bounded away from infinity and zero, for \( l = 1, \ldots, n \). Under this alternative, we can show that \( J_u - J_{CZZ} = o_p(1) \), which in turn implies that \( J_u \) and \( J_{CZZ} \) have the same power properties. Define \( \delta_1 = 1 - \frac{n^2(\Sigma_n)}{\text{tr}(\Sigma_n)} \) and \( \delta_2 = \text{tr} \left( \frac{\Sigma^2}{n(\Sigma_n)} - \frac{\Sigma_n}{n(\Sigma_n)} \right)^2 \). One can show that \( T\delta_1 \xrightarrow{} \infty \) and \( T\delta_2/(T\delta_1) \xrightarrow{} 0 \) as \( (n,T) \to \infty \). This satisfies the conditions of Theorem 4 in Chen et al. (2010). By using this Theorem, the corresponding power function \( P(J_u \geq z_{\alpha} | \Sigma_n = (\sigma_i \sigma_j \rho^{j-i})_{n \times n}) \xrightarrow{} 1 \), as \( (n,T) \to \infty \), where \( z_{\alpha} \) is the upper quantile of \( N(0,1) \). Let us consider a special case under this alternative. More specifically, assume that \( \Delta = 0 \), \( \sigma_i = \sigma_j = \sigma_v \) for any \((i,j)\) and \( T/n \to 0 \) as \( (n,T) \to \infty \). It follows that \( \psi^{-1} \to \frac{T}{2} \) and \( (1 - \rho^2) J_u - T \rho^2/2 \xrightarrow{d} N(0,1) \).

5. Monte Carlo Simulations

We conduct Monte Carlo experiments to assess the empirical size and power of the \( J_u \) test proposed in this paper. We follow the design of Baltagi et al. (2011) and assume homoskedasticity on the remainder error term. In this case, the \( J_u \) test becomes a test for cross-sectional dependence. We also report the performance of \( J_{BFK} \) proposed by Baltagi et al. (2011) for comparison purposes.

5.1. Experiment Design

Consider the following data-generating process:

\[
y_{it} = \alpha + \beta x_{it} + \mu_i + v_{it}, \quad i = 1, \ldots, n; \quad t = 1, \ldots, T, \tag{5.1}
\]

\[
x_{it} = \lambda x_{i,t-1} + \mu_i + \eta_{it}, \tag{5.2}
\]
where $\mu_i$ is the fixed effects and $v_{it}$ is the idiosyncratic error, $\eta_{it} \sim i.i.d. \ N(\phi_\eta, \sigma^2_\eta)$. The regressor $x_{it}$ is allowed to be correlated with the $\mu_i$’s. This follows the design by Im et al. (1999).

To study the power of the tests, we consider two different types of cross-sectional dependence models: a factor model and a spatial model. For the factor model, see Pesaran (2004), Pesaran and Tosetti (2011), Baltagi et al. (2011), we assume:

$$v_{it} = \gamma_i f_t + \epsilon_{it},$$

where $f_t$ ($t = 1, \ldots, T$) are the factors and $\gamma_i$ ($i = 1, \ldots, n$) are the loadings. For the spatial model, we consider a first-order spatial autocorrelation model SAR(1), see Anselin and Bera (1998) and Baltagi et al. (2003), given by:

$$v_{it} = \delta(0.5v_{i-1,t} + 0.5v_{i+1,t}) + \epsilon_{it}.$$  

The $\epsilon_{it}$ in (5.3) and (5.4) are assumed to be $i.i.d.$ $N(0, \sigma^2)$ across individuals and over time. Under the null, we have $\gamma_i = 0$ and $\delta = 0$.

Under the null, the $v_{it}$ comes from some $i.i.d.$ distribution across individuals and over time with mean zero and variance $\sigma^2_v$. These are not necessarily normally distributed. For models (5.1) and (5.2), we set $\alpha = 1$ and $\beta = 2$; $\mu_i$ is drawn from $i.i.d. \ N(\phi_\mu, \sigma^2_\mu)$ with $\phi_\mu = 0$ and $\sigma^2_\mu = 0.25$. We also set $\lambda = 0.7$, $\phi_\eta = 0$ and $\sigma^2_\eta = 1$. For models (5.3) and (5.4), $\gamma_i \sim i.i.d. \ U(-0.5, 0.55)$; $f_t$ is set to be $i.i.d. \ N(0,1)$ and $\delta = 0.4$. Various distributions are considered in generating the model errors, $v_{it}$ in (5.1) and $\epsilon_{it}$ in (5.3) and (5.4) are assumed be normal, lognormal, gamma, chi-squared with mean zero and variance 0.5.

The Monte Carlo experiments are conducted for $n = 20, 40, 60, 80, 100, 200, 400$ and $T = 20, 40, 60, 80$. We perform 1,000 replications to compute the $J_u$ and $J_{BFK}$ test statistics. We conduct the tests at the positive one-sided 5% nominal significance level to obtain the empirical size.

5.2. Results

Table 1 gives the empirical size of the $J_u$ and $J_{BFK}$ tests allowing $v_{it}$ to be generated from different distributions. When the disturbances are normally distributed, the size of $J_u$ and $J_{BFK}$ are both close to 5%, which is consistent with the theoretical results. The rest of Table 1 shows
the results with \( v_{it} \) coming from alternative non-normal distributions. The size of \( J_u \) is close to 5\% when \( n \) and \( T \) are large; for small \( n \) or small \( T \), it is slightly oversized. However, \( J_{BFK} \) is no longer robust to non-normality and suffers from size distortions.

Table 2 presents the size adjusted power of the tests under the alternative specification of a factor model. Both tests have size adjusted power that is almost 1 when \( n \) and \( T \) are large with \( v_{it} \) normally distributed. For small \( n \) and small \( T \), the size adjusted power of \( J_u \) works as well as \( J_{BFK} \). Note that the size adjusted power of \( J_{BFK} \) is quite good even when \( n \) is a lot larger than \( T \) for the normal distribution scenario. However, for non-normal distributions, the size adjusted power of \( J_u \) is 1 as \( n \) and \( T \) become large; and it is larger than the size adjusted power of \( J_{BFK} \) for all \((n, T)\) combinations.

Table 3 reports the size adjusted power of both tests under the alternative specification of SAR(1). The results are similar to the factor model. \( J_u \) works as well as \( J_{BFK} \) for the normal distribution scenario, but better for all combinations of \( n \) and \( T \) for non-normal distribution scenarios.

6. Conclusion

Though the John test proposed by [Baltagi et al. (2011)] has been shown to perform well for a large panel data regression model with fixed effects, it relies heavily on the normality assumption. This paper proposes a new test, \( J_u \), for the null of sphericity of the disturbances which does not rely on the normality assumption. Instead of \( n/T \to c \), we allow \( n \) to be a larger order of \( T \) which is consistent with micro-panel data sets with “large \( n \) and small \( T \)”.

</tbody>
</table>

Note: This table computes the size adjusted power for a SAR(1) structure model that allows for cross-sectional dependence in the error. We conduct the simulation with four distributions: normal, gamma, lognormal and chi-squared with mean 0, and variance 0.5.
