Senior Thesis by Marco Antonio Ravini

Primary Advisor: Julie Larsen

Closed system design methodologies have produced infrastructures that anticipate only a single lifetime use. This approach has burdened many urban areas with defective infrastructures in need of perpetual modification and repair. Rather than continue to over-engineer these vital frameworks to *resist* the inevitable failure of individual components, the next generation of public infrastructure needs to exceed its technical specifications and seek ways to create spatial reciprocity among systems.

This thesis calls for a renewed understanding of redundancy in order to strategically infuse infrastructure with public agency and diverse utility. Such an approach has the potential to yield greater systemic outputs and a more productive lifespan, allowing future infrastructures to be positioned both as a collective good and a resilient service.

Infrastructures are inextricably linked to the development of cities and the delivery of improved living standards. These ideals are embedded within the typology of the bridge – a structure critical to the efficacy of transportation networks. Optimized to facilitate the continuous flow of people and goods, the present state of bridges forecasts a future of urban dysfunction. Over the last decade, bridges in the United States have become a significant feature in the growing crisis of public infrastructure. Built during the post-war era when the growth of transportation networks was less of an expansion and more of an explosion, many bridges have now exceeded their 50-year lifespan.

Via the prototyping and design of a new Liberty Bridge in Pittsburgh Pennsylvania, this thesis aims to demonstrate how infrastructural thickening might enable the next generation of public works to perform as resilient systems rather than standalone structures.

Infrastructural Thickening is the term I propose to describe a strategy that aims to modify the spatial, systemic and experiential utility of infrastructure – a strategy that works towards shifting the understanding of infrastructure from line to volume. This shift is achieved by virtue of de-optimization, a design technique that seeks to augment engineered specifications into scenarios for inhabitation, participation and added value.

In pursuit of infrastructural thickening, this thesis explores relationships between **structure**, **space** and form as a means to generate redundancies that have the capacity to address issues beyond the bridge's physical footprint. Topics such as storm water run-off, waste management, and public space are central to the design agenda. In response to these urgent issues, a **system of structural cones** is deployed that mediate flows of water, cars and people into a unified, heterogeneous interlace.

This thesis envisions the next generation of infrastructure as thick matter – a new public territory that provides people the oppurtunity to engage and participate in mutually productive dialogues with issues of urban, spatial and environmental urgency.

Designing the Chunnel

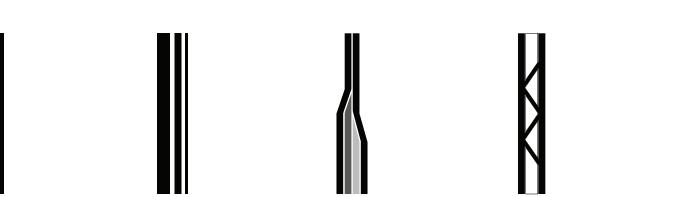

Redundancies beyond idleness

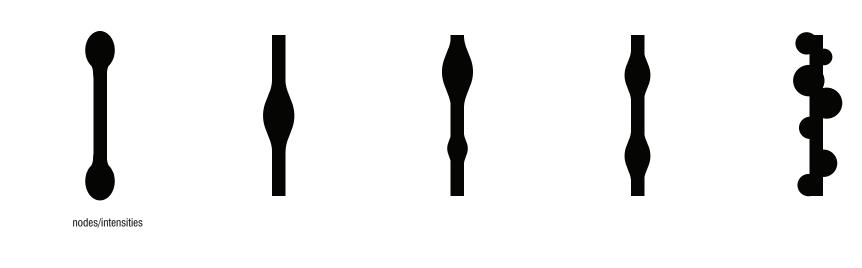

Design Technique: De-Optimization

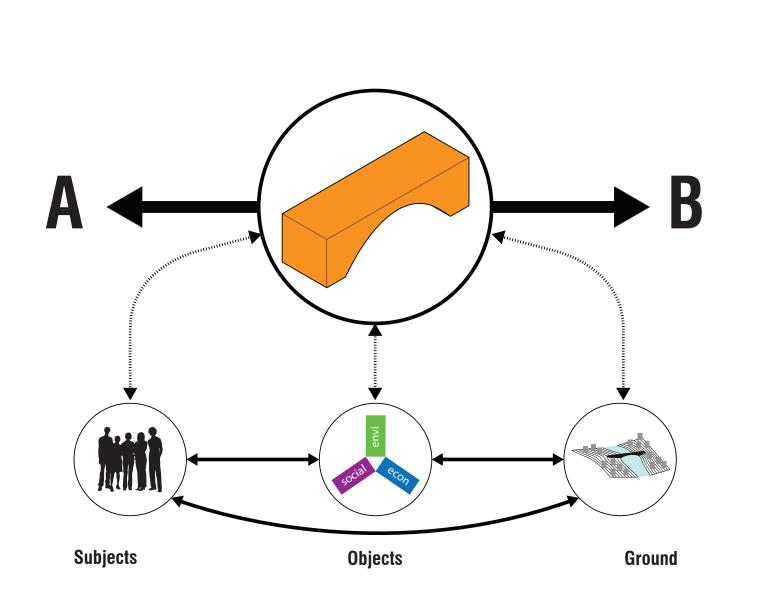

The bridge is a linear surface constructed from a repetitive assembly of structural components. Its primary purpose is to facilitate the continuous flow of vectors (people and cars) and processes (mobility) between two nodes.

Since a bridge is fundamentally an aggregate of structural modules, how can we utilize structure to maximize surface porosity and also facilitate rainwater flow?

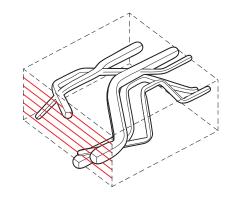

Horizontal aggregation of vertical elements Maximizes Surface Porosity, Minimizes Structural Footprint (However, it dissolves horizontality, halts flow of people and cars)

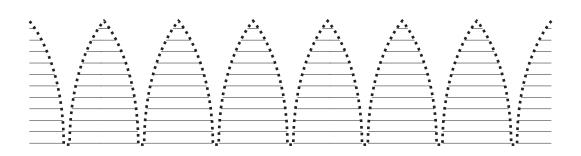

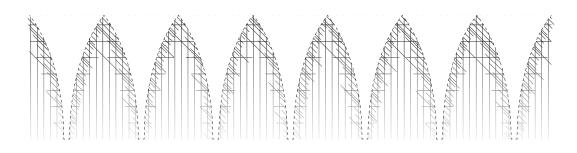

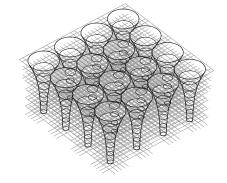

Unified Interlace Multiplicity of horizontal planes allows for various flows to weave and traverse both in <u>plan</u> and in <u>section</u>.

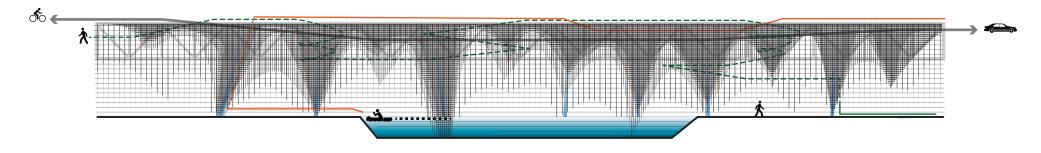

Composite Structure Merging cones with horizontal structure

Structural Gradation (x, y, z) Add structure where needed, remove where not needed

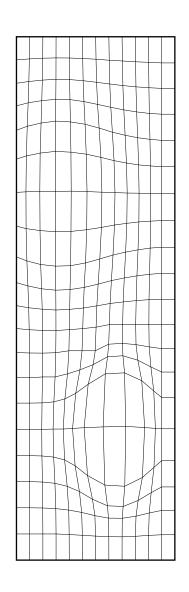

The structure is no longer distinguished by its basic subdivisions. Instead, through the process of infrastructrural thickening, the bridge begins to express a whole-to-whole relationship; a fine grained structural lattice that enables people, water and cars to participate in the issue of volume.

BRIDGE AS WATER NEXUS Process

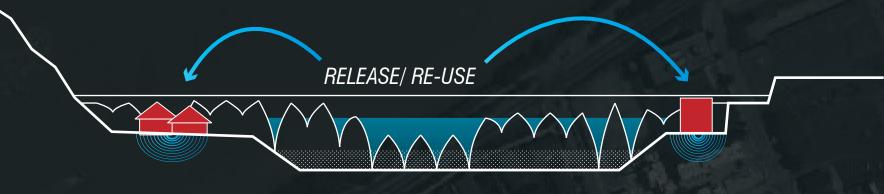

\$**4**%

Proposed

Existing

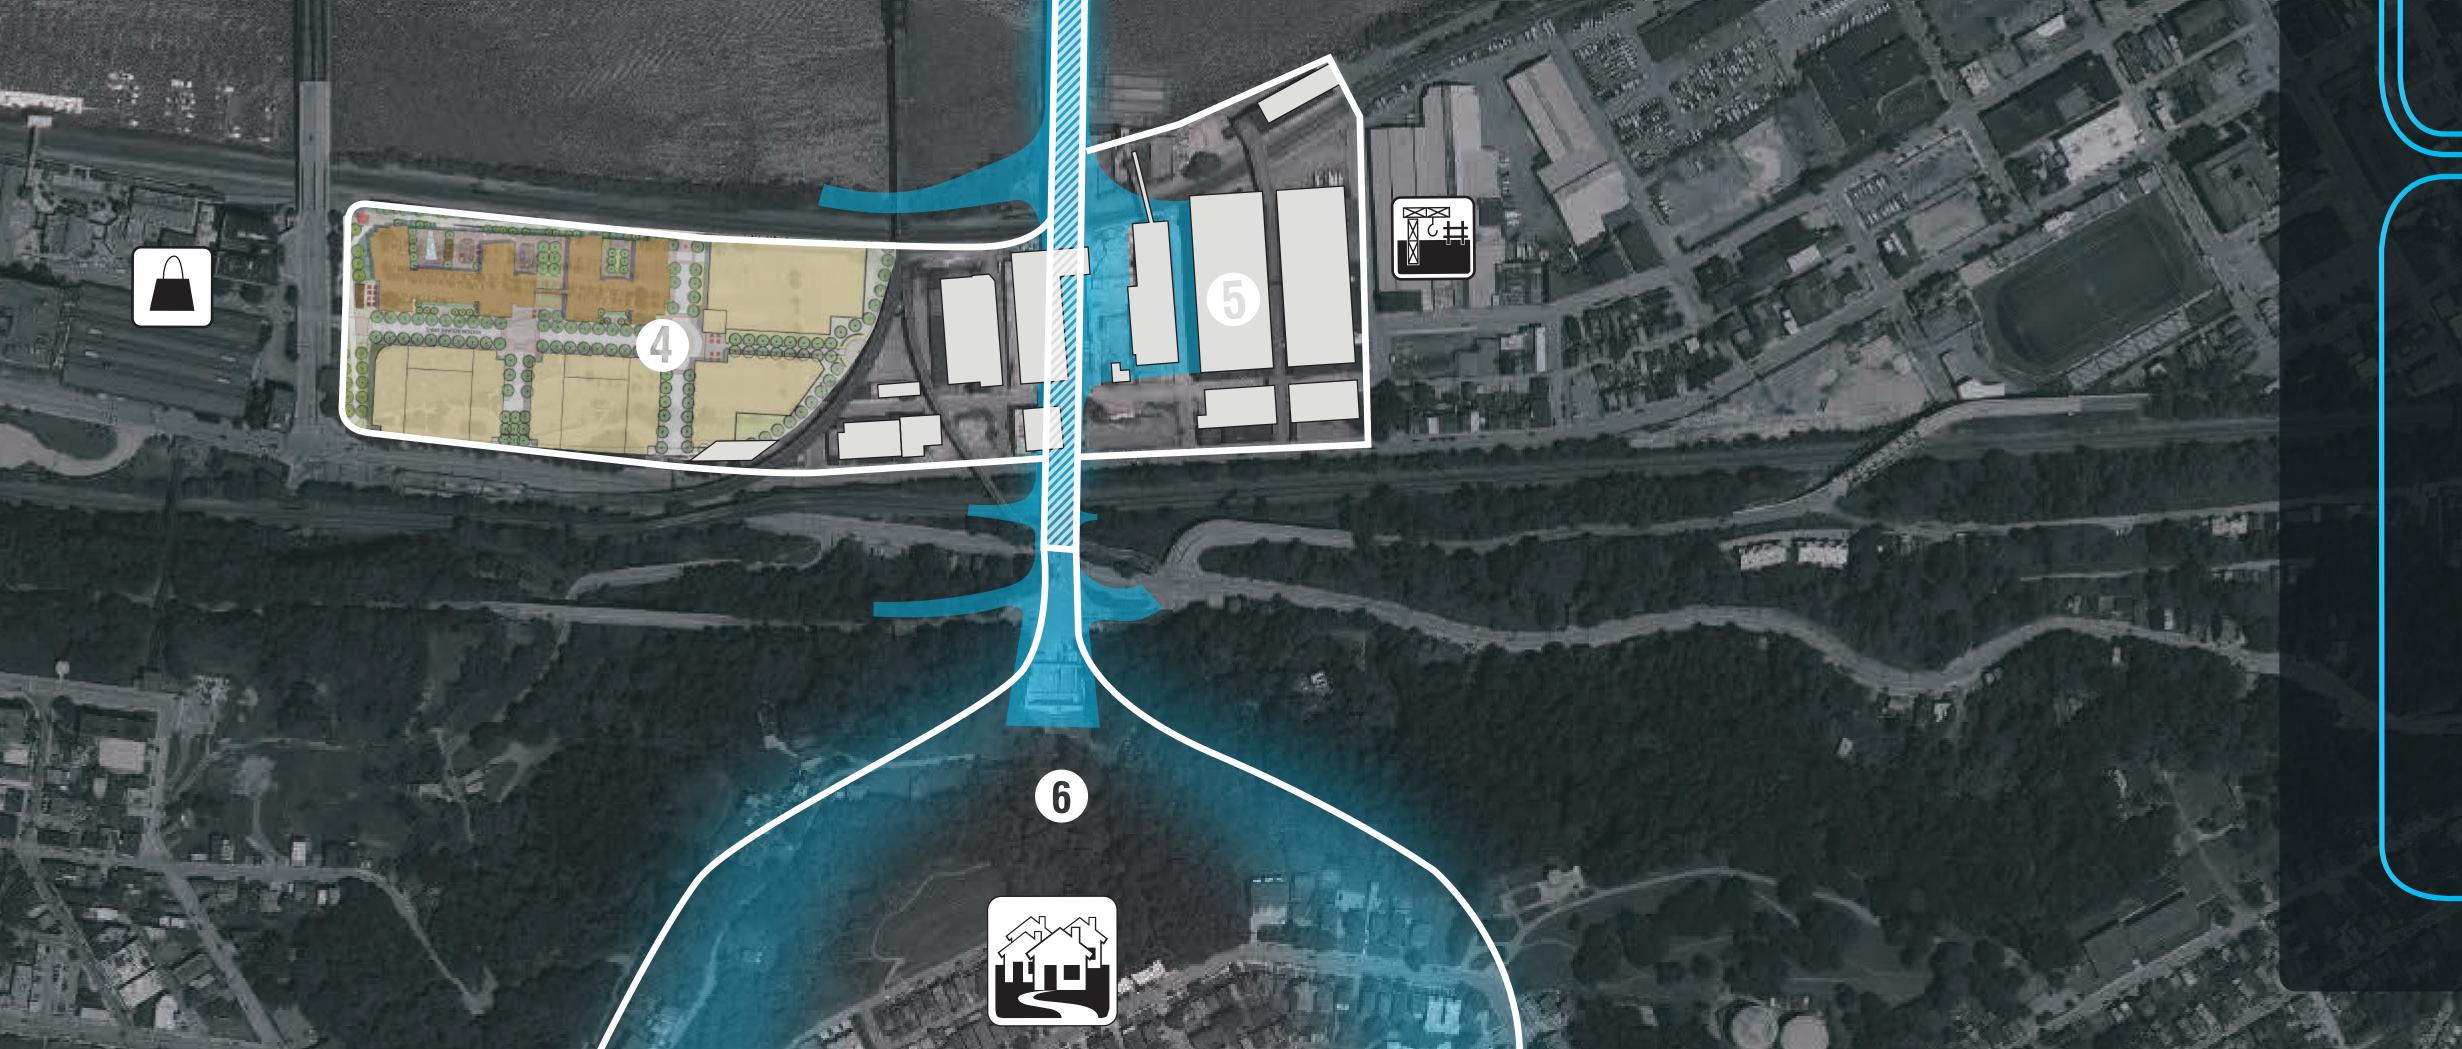

The site of old 28-acre Mellon Area has been proposed to be transformed into a mixed-use development. Utilizing the elevation of the site, rainwater run-off could be channeled to the bridge for collection and processing.

This convergence of highway ramps is bounded between Duquesne University and the Downtown area. Further accumulation of rainwater can be guided to the bridge structure for storing and processing.

This underutilized and crucial public space nested 3 between the Municipal Courthouse and the country Jail has the potential to become part of the systemic logic of the bridge. Water based activities and habitats can be introduced in order to create a more productive space for

public engagement.
