Abstract—This paper generalizes Wyner’s definition of common information of a pair of random variables to that of $N$ random variables. We prove coding theorems that show the same operational meanings for the common information of two random variables generalize to that of $N$ random variables. As a byproduct of our proof, we show that the Gray-Wyner source coding network can be generalized to $N$ source sequences with $N$ decoders. We also establish a monotone property of Wyner’s common information which is in contrast to other notions of the common information, specifically Shannon’s mutual information and Gács and Körner’s common randomness. Examples about the computation of Wyner’s common information of $N$ random variables are also given.

I. INTRODUCTION

Consider a pair of dependent random variables $X$ and $Y$ with joint distribution $P(x,y)$. Characterizing the common information between $X$ and $Y$ has been a topic of research interest in the past decades [1]–[5]. There have been three classical notions reported in the literature.

Shannon’s [6] mutual information $I(X;Y)$

Shannon’s mutual information measures how much uncertainty can be reduced with respect to one random variable by observation the other random variable. In the case that $X$ and $Y$ are independent, mutual information $I(X;Y) = 0$, indicating that observing one variable $X$ does not give any information about $Y$ and vice versa. Shannon’s mutual information carries operational meanings that are instrumental in laying the foundation for information theory.

Gács and Körner’s [1] common randomness $K(X,Y)$

Consider a pair of independent and identically distributed random sequences $X^n, Y^n$ with each pair $(X_i, Y_i) \sim P(x,y)$. These two sequences are observed respectively by two nodes, which attempt to map the sequences onto a common message set $W$. Specifically, let $f_n$ and $g_n$ be such mappings, i.e.,

$$f_n : X^n \rightarrow W,$$

$$g_n : Y^n \rightarrow W.$$

Define $\epsilon_n = Pr(W_1 \neq W_2)$ where $W_1 = f_n(X^n)$ and $W_2 = g_n(Y^n)$. Gács and Körner’s common randomness is defined as

$$K(X,Y) = \lim_{n \rightarrow \infty, \epsilon_n \rightarrow 0} \sup \frac{1}{n} H(W_1).$$

Gács and Körner’s common randomness has found extensive applications in cryptography, i.e., for key generation [7]–[9]. On the other hand, the common randomness notion is rather restrictive as it equals 0 in most cases except for the following special case (or random variable pairs that can be converted to such distributions through relabeling of realizations, i.e., permutation of joint distribution matrix). Let $X$ and $Y$ be $X = (X', V)$ and $Y = (Y', V)$, respectively, where $X', Y', V$ are independent. Clearly, the common part between $X$ and $Y$ is $V$ and it follows that $K(X;Y) = H(V)$. Note that for this example $I(X;Y) = K(X;Y) = H(V)$.

Wyner’s [4] common information $C(X,Y)$

Wyner’s common information is defined as

$$C(X,Y) = \min_{X \rightarrow W \rightarrow Y} I(XY;W).$$

Thus the hidden (or auxiliary) variable $W$ induces a Markov chain $X \rightarrow W \rightarrow Y$, or, equivalently, a conditional independence structure of $X, Y$ being independent given $W$. Wyner gave two operational meanings for the above definition. The first approach is shown in Fig. 1. The encoder observes a pair of sequences $(X^n, Y^n)$, and map them to three messages $W_0, W_1, W_2$, taking values in alphabets of respective sizes $2^{nR_0}, 2^{nR_1}, 2^{nR_2}$. Decoder 1, upon receiving $(W_0, W_1)$, needs to reproduce $X^n$ reliably while decoder 2, upon receiving $(W_0, W_2)$, needs to reproduce $Y^n$ reliably. Let $C_1$ be the liminf of all admissible $R_0$ for the system in Fig. 1 such that the total rate $R_0 + R_1 + R_2 \approx H(X,Y)$.

The second approach is shown in Fig. 2. A common input $W$, uniformly distributed on $W = \{1, \ldots, 2^{nR_0}\}$ is given to two separate processors which are otherwise independent of each other. These processors (random variable generators) generating independent and identically distributed sequences according to $q_1(X|W)$ and $q_2(Y|W)$ respectively. The output sequences of the two processors are denoted by $\tilde{X}^n$ and $\tilde{Y}^n$ respectively. Thus the joint distribution of the output sequences is,

$$Q(\tilde{X}^n, \tilde{Y}^n) = \sum_{w \in W} \frac{1}{W} q_1(X^n|W)q_2(Y^n|W).$$

Define $C_2$ of $(X,Y)$ to be infimum of rate $R_0$ for the common input such that $q(\tilde{X}^n, \tilde{Y}^n)$ close to $p(X^n, Y^n)$, where the closeness is defined using the average divergence of the two distributions

$$D_n(P, Q) = \frac{1}{n} \sum_{x^n \in X^n, y^n \in Y^n} P(x^n, y^n) \log \frac{P(x^n, y^n)}{Q(x^n, y^n)}.$$

Wyner proved that

$$C_1 = C_2 = C(X,Y).$$

It was observed in [4] that

$$K(X,Y) \leq I(X;Y) \leq C(X,Y).$$
Wyner [4] and Witsenhausen [5] also provide several examples on how to calculate the common information $C(X, Y)$. For the example of $X = (X', V)$ and $Y = (Y', V)$ with $(X', Y', V)$ mutually independent, $C(X, Y) = I(X; Y) = K(X, Y) = H(V)$.

Generalizing of mutual information to $N$ random variables was first reported in [10]. The generalization comes from the observation that for a pair of random variables, Shannon’s information measures is consistent with the Venn diagram for set operation and a comprehensive treatment was available in [11], [12]. Gács and Körner’s common randomness was recently generalized to multiple random variables by Tyagi, Narayan and Gupta in [13], which extends the encoding process in the definition of common randomness to that of $N$ terminals.

In this paper, we generalize Wyner’s common information of a pair of random variables to that of $N$ dependent variables. We show that the operational meaning defined in both approaches are still valid. Moreover, we establish some monotone property of such generalization which contrast to the notion of ‘common’ information. Specifically, we show that the common information does not decrease as the number of variables increases while keeping the same marginal distribution. This is different from the other two notions of common information. Examples on evaluating $C(X_1, X_2, \cdots, X_N)$ are given for circularly symmetric binary sources and the asymptotic results are also studied.

The rest of this paper is organized as follows. Section II gives the problem formulation and main results. Section III gives some examples and discussions. Section IV concludes the paper.

II. PROBLEM STATEMENT AND MAIN RESULTS

Let $X_1, X_2, \cdots, X_N$ be random variables that take values on the finite alphabet sets $\mathcal{X}_1, \mathcal{X}_2, \cdots, \mathcal{X}_N$ with joint distribution $P(x_1, x_2, \cdots, x_N)$. Our generalization of Wyner’s common information is to define a similar measure for $N$ random variables by preserving the conditional independence structure through the introduction of an auxiliary random variable. Specifically, we define

$$C(X_1, X_2, \cdots, X_N) \triangleq \inf I(X_1, X_2, \cdots, X_N; W),$$

where the infimum is taken over all the joint distributions of $(X_1, X_2, \cdots, X_N, W)$ such that

$$\sum_w P(x_1, x_2, \cdots, x_N, w) = P(x_1, x_2, \cdots, x_N),$$

$$P(x_1, \ldots, x_N | w) = \prod_{i=1}^{n} P(x_i | w).$$

Thus the marginal distribution of $(X_1, X_2, \cdots, X_N)$ is $P(x_1, x_2, \cdots, x_N)$ and $(X_1, \cdots, X_N)$ are conditionally independent given $W$.

We now give formal definitions of $C_1$ and $C_2$ for $N$ random variables. Consider $N$ length-$n$ independent and identical distributed source sequences $(x^n_1, x^n_2, \cdots, x^n_N)$ with $(X_{1i}, X_{2i}, \cdots, X_{Ni}) \sim p(x_1, x_2, \cdots, x_N)$, i.e.,

$$P^n(x^n_1, x^n_2, \cdots, x^n_N) = \prod_{i=1}^{n} P(x_{1i}, x_{2i}, \cdots, x_{Ni}).$$

For the Gray-Wyner source coding network, we start with the definition of encoder-decoders.

Definition 1: A $(n, M_0, M_1, \cdots, M_N)$ code consists of the following:

- An encoder mapping

$$f : \mathcal{X}_1^n \times \mathcal{X}_2^n \times \cdots \times \mathcal{X}_N^n \rightarrow M_0 \times M_1 \times \cdots \times M_N,$$

where $M_i = \{1, 2, \cdots, 2^{nR_i}\}$.

- $N$ decoders $g_i$, for $i = 1, 2, \cdots, N$,

$$g_i : M_i \times M_0 \rightarrow \mathcal{X}_i^n.$$  

The probability of error is defined as

$$P_c(n) = Pr\{\hat{X}_1^n \times \hat{X}_2^n \times \cdots \times \hat{X}_N^n \neq (X_1^n, X_2^n, \cdots, X_N^n)\}.$$  

where $\hat{X}_i^n = g_i(M_i, M_0)$ for $i = 1, \cdots, N$.

Definition 2: A number $R_0$ is said to be achievable if for any $\epsilon > 0$, we can find an $n$ sufficiently large such that there exists a $(n, M_0, M_1, \cdots, M_N)$ code with

$$M_0 \leq 2^{nR_0}$$

$$P_c(n) \leq \epsilon,$$

$$\frac{1}{n} \sum_{i=0}^{N} \log M_i \leq H(X_1, X_2, \cdots, X_N) + \epsilon.$$  

As with the case for two random variables, $C_1$ is defined as the infimum of all achievable $R_0$.

For the second approach of approximating joint distribution, we again start with the following definition.

Definition 3: An $(n, M, \Delta)$ generator consists of the following:

- a message set $W \in \{1, 2, \cdots, 2^{nR}\}$;
for all \( w \in W \) and \( N \) conditional probability distributions \( q^{(n)}(x^n_i | w) \), for \( i = 1, 2, \ldots, N \), define the probability distribution on \( \mathcal{X}_1^n \times \mathcal{X}_2^n \times \cdots \times \mathcal{X}_N^n 
abla \)

\[
Q^{(n)}(X_1^n, X_2^n, \ldots, X_N^n) = \sum_{w \in W} \frac{1}{\mathcal{M}} \prod_{i=1}^{N} q^{(n)}(x^n_i | w).
\tag{15}
\]

Thus the \( N \) processors serve as random number generators each generating independent and identically distributed (i.i.d.) sequence \( \hat{X}_i^n \) according to \( q(x^n_i | w) \) and the output of the processors follow joint distribution defined in (9). Let

\[
\Delta = D_n(P^{(n)}; Q^{(n)}) = \frac{1}{n} \sum_{x^n_i \in X^n_i} P^{(n)}(x^n_i) \log \frac{P^{(n)}(x^n_i)}{Q^{(n)}(x^n_i)},
\tag{16}
\]

where \( P^{(n)} \) and \( Q^{(n)} \) are defined as in (9) and (15) respectively.

**Definition 4:** A number \( R \) is said to be achievable if for all \( \epsilon > 0 \), we can find an \( n \) sufficiently large such that there exists a \( (n, \mathcal{M}, \Delta) \) generator with \( \mathcal{M} \leq 2^nR \) and \( \Delta \leq \epsilon \).

We define \( C_2 \) as the infimum of all achievable \( R \).

The main result of this paper is the following theorem.

**Theorem 1:**

\[
C_1 = C_2 = C(X_1, X_2, \ldots, X_N). \tag{17}
\]

The proof of Theorem 1 is given in the Appendix. Thus both \( C_1 \) and \( C_2 \) admit single letter characterization which coincides with \( C(X_1, \ldots, X_N) \).

### III. Examples and Discussions

We start with the following example. Let \( X = (X', U, V) \), \( Y = (Y', V, W) \) and \( Z = (Z', W, U) \) where the random variables \( X', Y', Z', U, V, W \) are mutually independent. It is easy to show that for this example

\[
I(X; Y, Z) = K(X, Y, Z) = 0,
\]

whereas

\[
C(X, Y, Z) = H(UVW).
\]

On the other hand,

\[
C(X, Y) = H(V),
\]

\[
C(X, Z) = H(U),
\]

\[
C(Y, Z) = H(W).
\]

What is interesting is that the inclusion of an additional variable increases the common information. This is somewhat surprising: if the information is common it ought to be non-increasing when more random variables are included. Indeed, we can prove the following general result:

**Lemma 1:** Let \((X_1, \ldots, X_N) \sim p(x_1, \ldots, x_N)\). For any two sets \( A, B \) that satisfy \( A \subseteq B \subseteq N = \{1, 2, \ldots, N\} \)

\[
C(X_A) \leq C(X_B), \tag{18}
\]

where \( X_A = \{X_i, i \in A\} \) and \( X_B = \{X_i, i \in B\} \).

**Proof:** Let \( W' \) be the \( W \) that achieves \( C(X_B) \), i.e.,

\[
I(W'; X_B) = \inf I(W; X_B). \] But \( A \subseteq B \), thus \( X_B \) conditionally independent given \( W' \) implies that \( X_A \) is conditionally independent given \( W' \). Thus

\[
I(X_B; W') \geq I(X_A; W') \geq \inf I(X_A; W)
\]

where the infimum is taken over all \( W \) such that \( X_A \) is independent given \( W \).

This monotone property perhaps suggests that the name common information, while meaningful for pair of variables, no longer suits the generalization to \( N \) variables. We comment here that Gács and Körner’s common randomness follows a different monotone property

\[
K(X_A) \geq K(X_B)
\]

while there is no definitive inequality relationship for mutual information.

As a consequence, we have for any \( N \) random variables

\[
C(X_1, X_2, \ldots, X_N) \geq K(X_1, X_2, \ldots, X_N).
\]

We now examine another example in which Wyner’s common information increases as the number of the observations increases. Moreover the common information eventually converges and the asymptote suggests that the notion of common information may have potential application in certain inference problems.

Consider first the example of three binary random variables \( X_1, X_2, X_3 \) with joint distribution

\[
P(x_1, x_2, x_3) = \begin{cases} \frac{1}{2} - \frac{3}{4}a_0 & \text{if } x_1 = x_2 = x_3 \\ \frac{1}{4}a_0 & \text{otherwise} \end{cases} \tag{19}
\]

where the parameter \( a_0 \) satisfies \( 0 \leq a_0 \leq \frac{1}{2} \).

It can be easily verified that

\[
Pr\{X_i = 0\} = \frac{1}{2}, \tag{20}
\]

for \( i = 1, 2, 3 \) and that for \( 1 \leq i, j \leq 3, i \neq j \),

\[
Pr\{X_i = x_i, X_j = x_j\} = \frac{1}{2}(1 - a_0)\delta_{x_i, x_j} + \frac{1}{2}a_0(1 - \delta_{x_i, x_j}), \tag{21}
\]

where \( \delta_{a,b} = 1 \) if \( a = b \) and 0 otherwise.

Thus, each pair of \( \{X_i, X_j\}, i \neq j \), can be viewed as a doubly symmetric binary source as defined in [4]. We refer to this set of exchangeable binary sources circularly symmetric binary source. For such circularly symmetric binary source \( (X_1, X_2, X_3) \) with joint distribution given in (19) and random variables \( (X_1, X_2, X_3, W) \) that satisfy (7) and (8), we have the following lemma.

**Lemma 2:**

\[
H(X_1 | W) + H(X_2 | W) + H(X_3 | W) \leq 3h(a_1), \tag{22}
\]

where \( a_1 = \frac{1}{2} - \frac{1}{4}(1 - 2a_0)^{\frac{1}{2}} \).
This lemma is a direct consequence of Wyner’s result on doubly symmetric binary source [4]. Therefore, we have,

\[ I(X_1X_2X_3; W) = H(X_1X_2X_3) - H(X_1X_2X_3|W), \]
\[ = H(X_1X_2X_3) - \sum_{i=1}^{3} H(X_i|W), \]
\[ \geq H(X_1X_2X_3) - 3h(a_1), \]
\[ = 1 + h(a_0) + a_0 + (1 - a_0)h\left(\frac{a_0}{2(1 - a_0)}\right) - 2h(a_1), \]

(23)

This lower bound can indeed be achieved by choosing the following random variables. Let \( W \) be a random variable with \( p_W(0) = p_W(1) = 1/2 \), i.e., a Bernoulli(1/2) random variable. Let each \( X_i \) be the output of a binary symmetric channel (BSC) with crossover probability \( a_1 \) with \( W \) as input. The channels share the common input \( W \) but are otherwise independent of each other. This is illustrated in the simple Bayesian graph model in Fig. 3 with \( N = 3 \) where each link represents a BSC with crossover probability \( a_1 \).

Thus, the common information of this circularly symmetric binary source is,

\[ C(X_1X_2X_3) = 1 + a_0 + h(a_0) + (1 - a_0)h\left(\frac{a_0}{2(1 - a_0)}\right) - 3h(a_1), \]

(24)

Notice that any pair of \( (X_i, X_j) \) is a doubly symmetric binary source [4], therefore,

\[ C(X, Y) = 1 + h(a_0) - 2h(a_1). \]

It is straightforward to check that

\[ C(X, Y, Z) > C(X, Y) \]

when \( 0 < a_0 < \frac{1}{2} \). This is also shown numerically in Fig. 4.

We now study the generalization of above example to arbitrary \( N \) and in particular the asymptotic value of the common information for the circularly symmetric binary sources.

Consider \( N \) binary random variables \( X_1, X_2, \ldots, X_N \) with joint distribution \( p(X_1, X_2, \ldots, X_N) \) generated by an underlying Bayesian graph model as in Fig. 3, where \( W \) is a

Bernoulli(1/2) random variable and each \( X_i, i = 1, 2, \ldots, N, \) is the output of a BSC with crossover probability \( a_1(0 \leq a_1 \leq \frac{1}{2}) \) with a common input \( W \). Hence, for \( x_1, x_2, \ldots, x_N \in \{0, 1\} \),

\[ p(x_1, x_2, \ldots, x_n) = \sum_{w \in \{0,1\}} \frac{1}{2} \prod_{i=1}^{N} P_i(x_i|w), \]

(25)

where for each \( i = 1, 2, \ldots, N, p_i(x_i|w) = (1 - a_1) \) if \( x_i = w \) and \( a_1 \) otherwise.

Similarly, we have,

\[ \sum_{i=1}^{N} H(X_i|W) \leq Nh(a_1), \]

(26)

for any random variable \( W \) that satisfies (7) and (8).

Therefore, \( C(X_1, X_2, \ldots, X_N) \) can be lower bounded by

\[ C(X_1, X_2, \ldots, X_N) \geq H(X_1, X_2, \ldots, X_N) - Nh(a_1), \]

(27)

On the other hand, the above lower bound is achievable by exactly the same \( W \) in the above Bayesian model. Hence, we have,

\[ C(X_1, X_2, \ldots, X_N) = H(X_1, X_2, \ldots, X_N) - Nh(a_1), \]

(28)

where \( H(X_1, X_2, \ldots, X_N) \) can be calculated from (25).

Now consider the above model but with increasing \( N \). For any \( \epsilon > 0 \), it is clear that

\[ H(W|X_1, X_2, \ldots, X_N) < \epsilon \]

for \( N \) sufficiently large. This can be established by the Fano’s inequality as one can estimate \( W \) with arbitrary reliability given \( X_1, \ldots, X_N \) for sufficiently large \( N \). Therefore,

\[ C(X_1, X_2, \ldots, X_N) \]
\[ = H(X_1, X_2, \ldots, X_N) - Nh(a_1), \]
\[ = H(X_1, X_2, \ldots, X_N, W) - Nh(a_1) \]
\[ - H(W|X_1, X_2, \ldots, X_N), \]
\[ \geq H(W) - \epsilon, \]

(29)
where the last step is from the fact that
\[ H(X_1, X_2, \cdots, X_N | W) = N \hat{h}(a_1). \]
On the other hand,
\[ C(X_1, \cdots, X_N) \leq H(W) \]
for any \( N \). Thus, for \( a_1 < 1/2 \),
\[ \lim_{N \to \infty} C(X_1, X_2, \cdots, X_N) = H(W) = 1 \]
If \( a_1 = 1/2 \), then \( X_1, \cdots, X_N \) are mutually independent
hence \( C(X_1, \cdots, X_N) = 0 \).

IV. Conclusions
This paper generalized Wyner’s common information, defined
for a pair of random variables, to that of \( N \) dependent random variables. We showed that it is the minimum common
information rate \( R_0 \) needed for \( N \) separate decoders to recover
their intended sources losslessly while keeping the total rate
close to the entropy bound. It is also equivalently to the smallest
rate of the common input to \( N \) independent processors
(random number generators), such that the output distribution
is approximately the same as the given joint distribution. It
was shown that such generalization leads to the phenomenon
of ‘common’ information non-decreasing as the number of
sources increases.

For the example of circular symmetric binary sources, we
show that common information not only increases as \( N \) grows,
but eventually converges to the entropy of \( W \) that achieves
\( C(X_1, \cdots, X_N) \).

APPENDIX
In this appendix, we give the proof of Theorem 1. First, as
with [4], we define a quantity \( \Gamma(\delta_1, \delta_2) \) which plays an
important role in the proof.

Let \( (X_1, X_2, \cdots, X_N) \sim P(x_1, x_2, \cdots, x_N) \) where \( X_1, \cdots, X_N \) take values in finite alphabet \( A_1, \cdots, A_N \).
Let \( (\hat{X}_1, \hat{X}_2, \cdots, \hat{X}_N, W) \) be a \((N+1)\)-tuple of random
variables where \( \hat{X}_1 \in A_1, \hat{X}_2 \in A_2, \cdots, \hat{X}_N \in A_N \) and
\( W \in \mathcal{W} \), a finite set. Denote the marginal distribution of
\((\hat{X}_1, \hat{X}_2, \cdots, \hat{X}_N)\) by
\[ Q(x_1, x_2, \cdots, x_N) = Pr(\hat{X}_1 = x_1, \hat{X}_2 = x_2, \cdots, \hat{X}_N = x_N), \]
for \( x_i \in A_i, i = 1, 2, \cdots, N \).

For any \( \delta_1, \delta_2 \geq 0 \), define
\[ \Gamma(\delta_1, \delta_2) = \sup H(\hat{X}_1, \hat{X}_2, \cdots, \hat{X}_N | W), \]
where the supremum is taken over all \((N+1)\)-tuples
\((\hat{X}_1, \hat{X}_2, \cdots, \hat{X}_N, W)\) that satisfy
\[ D(P; Q) = \sum_{x_1, x_2, \cdots, x_N} P(x_1, x_2, \cdots, x_N) \log \frac{P(x_1, x_2, \cdots, x_N)}{Q(x_1, x_2, \cdots, x_N)} \leq \delta_1, \]
and
\[ \sum_{i=1}^N H(\hat{X}_i | W) - H(\hat{X}_1, \hat{X}_2, \cdots, \hat{X}_N | W) \leq \delta_2. \]

It follows that \( C(X_1, X_2, \cdots, X_N) \) as defined in Theorem 1,
is equivalent to
\[ C(X_1, X_2, \cdots, X_N) = H(X_1, X_2, \cdots, X_N) - \Gamma(0, 0). \]

The following lemma gives some properties of \( \Gamma(\delta_1, \delta_2) \).

**Lemma 3:** 1) For all \( \delta_1, \delta_2 \geq 0 \), there exists a \((N+1)\)-tuple
\( (X_1, X_2, \cdots, X_N, W) \) such that (32) and (33) are satisfied
\[ \Gamma(\delta_1, \delta_2) = H(\hat{X}_1, \hat{X}_2, \cdots, \hat{X}_N | W). \]
Moreover, for \( \delta_1, \delta_2 = 0 \),
\[ |\mathcal{W}| \leq \prod_{i=1}^N |A_i|. \]

2) \( \Gamma(\delta_1, \delta_2) \) is a concave function of \( (\delta_1, \delta_2) \) and it is
continuous for all \( \delta_1, \delta_2 \geq 0 \).
3) For \( \delta \geq 0 \), define \( \Gamma_1(\delta) = \Gamma(0, \delta) \) and \( \Gamma_2(\delta) = \Gamma(\delta, 0) \),
then \( \Gamma_1(\delta) \) and \( \Gamma_2(\delta) \) are concave and continuous for \( \delta \geq 0 \).

The proof of Lemma 1 follows similarly as the proof of
Theorem 4.4 in [4].

A. Proof of \( C_1 \geq C(X_1, X_2, \cdots, X_N) \).

In this section, we prove the first part of Theorem 1, that is
\( C_1 = C(X_1, X_2, \cdots, X_N) \). We first prove the converse part,
that is for any \( R_0 \) that is achievable for the Gray-Wyner source
coding network, we have,

**Theorem 2 (Converse):**
\[ C_1 \geq C(X_1, X_2, \cdots, X_N) \]

To prove the converse, first let \((f_i, g_i), i = 1, 2, \cdots, N\) be any \((n, M_0, M_1, \cdots, M_N)\) code that satisfies (12), (13) and
(14).

Then, we have,
\[ \log M_0 \geq H(M_0), \]
\[ \geq I(X_1^n X_2^n \cdots X_N^n; M_0), \]
\[ = H(X_1^n X_2^n \cdots X_N^n) - H(X_1^n X_2^n \cdots X_N^n | M_0), \]
\[ = nH(X_1 X_2 \cdots X_N) - \sum_{j=1}^n H(X_{1j} X_{2j} \cdots X_{N_j} | W_j), \]
where \( W_j \triangleq (M_0, X_1^{j-1}, X_2^{j-1}, \cdots, X_N^{j-1}) \) and
\( X_i^{j-1} = (X_{ij}, X_{i2}, \cdots, X_{i,j-1}) \) for \( i = 1, 2, \cdots, N \).

Notice that, the \((N+1)\)-tuple \((X_1, X_2, \cdots, X_N, W_j)\)
satisfies condition (32) and (33) with \( \delta_1 = 0 \) and
\[ \delta_2(j) = \sum_{i=1}^N H(X_{ij} | W_j) - H(X_{1j}, X_{2j}, \cdots, X_{Nj} | W_j). \]

Hence, by the definition of \( \Gamma(\delta_1, \delta_2) \), we have
\[ H(X_{1j} X_{2j} \cdots X_{Nj} | W_j) \leq \Gamma_1(\delta_2(j)). \]
Substitute (43) into (41), we get,
\[ \log M_0 \geq nH(X_1 X_2 \cdots X_N) - \sum_{j=1}^n \Gamma_1(\delta_2(j)) \]
\[ \geq nH(X_1 X_2 \cdots X_N) - n\Gamma_1(\frac{1}{n} \sum_{j=1}^n \delta_2(j)). \]
where the last step is from the concavity of $\Gamma_1(\cdot)$ function. Now define

$$\eta = \frac{1}{n} \sum_{j=1}^{n} \delta_2^{(j)}. \quad (46)$$

The following lemma gives an upper bound on $\eta$.

**Lemma 4:** For any $(n, M_0, M_1, \ldots, M_N)$ code that satisfies (12), (13) and (14), we have

$$\eta \leq (N+1)\epsilon. \quad (47)$$

**Proof:**

By Fano’s inequality, we have, for $i = 1, 2, \ldots, N$,

$$H(X^n_i|M_0 M_i) \leq n\epsilon. \quad (48)$$

Hence, we have, for $i = 1, 2, \ldots, N$,

$$\log M_i \geq H(M_i), \quad (49)$$

$$\geq H(M_i|M_0), \quad (50)$$

$$= H(X^n_i|M_i|M_0) - H(X^n_i|M_i|M_0)_0, \quad (51)$$

$$\geq H(X^n_i|M_i|M_0) - n\epsilon, \quad (52)$$

$$= H(X^n_i|M_0) - n\epsilon. \quad (53)$$

Then, we get,

$$\sum_{i=1}^{N} \log M_i \geq \sum_{i=1}^{N} H(X^n_i|M_0) - n\epsilon'. \quad (54)$$

where $\epsilon' = N\epsilon$. Together with (41), we get,

$$\sum_{i=0}^{N} \log M_i \geq n H(X_1 X_2 \cdots X_N)$$

$$- \sum_{j=1}^{n} H(X_{1j} X_{2j} \cdots X_{Nj}|W_j)$$

$$+ \sum_{i=1}^{N} H(X^n_i|M_0) - n\epsilon'. \quad (55)$$

Together with (14), we get,

$$\sum_{i=1}^{N} H(X^n_i|M_0) - \sum_{j=1}^{n} H(X_{1j} X_{2j} \cdots X_{Nj}|W_j) \leq n\epsilon''. \quad (56)$$

where $\epsilon'' = (N+1)\epsilon$. On the other hand, we have,

$$\sum_{i=1}^{N} H(X^n_i|M_0)$$

$$= \sum_{i=1}^{N} \sum_{j=1}^{n} H(X_{ij}|X_{i}^{j-1} M_0), \quad (57)$$

$$\geq \sum_{i=1}^{N} \sum_{j=1}^{n} H(X_{ij}|X_{i}^{j-1}, X_{2}^{j-1}, \ldots, X_{N}^{j-1}, M_0), \quad (58)$$

$$= \sum_{i=1}^{N} \sum_{j=1}^{n} H(X_{ij}|W_j). \quad (59)$$

Combine (56) and (59), we have,

$$\sum_{j=1}^{n} \left[ \sum_{i=1}^{N} H(X_{ij}|W_j) - H(X_{1j} X_{2j} \cdots X_{Nj}|W_j) \right] \leq n\epsilon''. \quad (60)$$

Hence, we have,

$$\frac{1}{n} \sum_{j=1}^{n} \delta_2^{(j)} \leq \epsilon''. \quad (61)$$

This completes the proof of Lemma 4. \(\Box\)

Now, from Lemma 4 and (45), we get,

$$R_0 \geq \frac{1}{n} \log M_0 \geq H(X_1, X_2, \cdots, X_N) - \Gamma_1(\eta). \quad (62)$$

Together with the continuity of $\Gamma_1(\cdot)$, we have, as $n \to \infty$,

$$R_0 \geq H(X_1, X_2, \cdots, X_N) - \Gamma_1(0), \quad (63)$$

$$= C(X_1, X_2, \cdots, X_N). \quad (64)$$

This completes the proof of converse part. \(\Box\)

We now prove the achievability part, that is, let the joint distribution $P(x_1, x_2, \cdots, x_N)$ be given, we have,

**Theorem 3 (Achievability):**

$$C_1 \leq C(X_1, X_2, \cdots, X_N). \quad (65)$$

Our proof mainly involves generalizing Gray-Wyner source coding network [14] to that of $N$ sources. The system model we considered here is the same as Fig. 1 described in section II except that definition 2 is replaced by,

**Definition 5:** A rate tuple $(R_0, R_1, \cdots, R_N)$ is said to be achievable if for all $\epsilon > 0$, we can find an $n$ sufficiently large such that there exists a $(n, 2^{nR_0}, 2^{nR_1}, \cdots, 2^{nR_N})$ code with

$$P_\epsilon^{(n)} \leq \epsilon. \quad (66)$$

Our purpose is to find all achievable rate tuples $(R_0, R_1, \cdots, R_N)$. The rate region of this source coding problem is summarized in the following theorem.

**Theorem 4:** For the source coding model described above, a rate tuple $(R_0, R_1, \cdots, R_N)$ is achievable if and only if the following conditions are satisfied,

$$R_0 \geq I(X_1, X_2, \cdots, X_N; W), \quad (67)$$

$$R_i \geq H(X_i|W), \quad (68)$$

for $i = 1, 2, \cdots, N$, and for some $W \sim P(w|x_1, x_2, \cdots, x_N)$, where $W \in W$ and $|W| \leq \prod_{i=1}^{N} |X_i| + 2$.

**Proof of Theorem 4 (Sketch):**

For the achievability part, we want to show that for any rate tuple $(R_0, R_1, \cdots, R_N)$ that satisfies above conditions, we can construct a $(n, 2^{nR_0}, 2^{nR_1}, \cdots, 2^{nR_N})$ code such that the decoding error $P_\epsilon^{(n)} \to 0$ as codeword length $n \to \infty$.

**Codeword Generation:** for any given distributions $P(x_1, x_2, \cdots, x_N)$ and $P(w|x_1, x_2, \cdots, x_N)$, we calculate the marginal distribution $P(w)$.

1) Codebook $C_0$: we first randomly generate $2^{nR_0}$ sequences $w^n$ i.i.d. $\sim P(w)$, and index them by $m_0 \in \{1, 2, \cdots, 2^{nR_0}\}$. 

2) Codebook $C(X_i)$: for each $i = 1, 2, \cdots, N$, for each
$x_i^n \in X_i^n$, randomly put them into $2^{nR_i}$ bins and index
them bins by $m_i \in \{1, 2, \cdots, 2^{nR_i}\}$.

Encoding:

1) for each source sequences $(x_1^n, x_2^n, \cdots, x_N^n)$, en-
coder $f_0$ finds a $w^n(m_0) \in C_0$ such that
$(x_1^n, x_2^n, \cdots, x_N^n, w^n(m_0)) \in T^n$, where $T^n$ is the
jointly typical set as defined in [15], and send the index
$m_0$ to the decoder. If there is no more than one $w^n$, 
choose the sequence $w^n$ with the smallest index; if there
exist no such sequence, choose sequence $w^n(1)$,

2) for $i = 1, 2, \cdots, N$, encoder $f_i$ sends the bin index $m_i$
of sequence $x_i^n$.

Decoding: for $i = 1, 2, \cdots, N$, decoder $i$ looks at bin $m_i$
for codebook $C(X_i)$ and finds the sequence $\hat{x}_i^n$ such that
$(\hat{x}_i^n, w^n(m_0)) \in T^n$. If there is more than one or none such
sequence, declare an error.

Error analysis: Assuming $m_i, i = 0, 1, \cdots, N$ are the
chosen indices for encoding $(x_1^n, x_2^n, \cdots, x_N^n)$. There are
three error events.

1) $E_1$: $(x_1^n, x_2^n, \cdots, x_N^n, w^n(m_0)) \notin T^n$ for all
$m_0 \in \{1, 2, \cdots, 2^{nR_0}\}$.

2) $E_2$: $(x_i^n, w^n(m_0)) \notin T^n$ for each $i$.

3) $E_3$: for some $i$, there exists $\hat{x}_i^n \neq x_i^n$ in bin $m_i$ of
codebook $C(X_i)$ such that $(\hat{x}_i^n, w^n(m_0)) \in T^n$.

Hence,

$$P_e^{(n)} \leq P(E_1) + P(E_2|E_1^c) + P(E_3|E_1^c, E_2^c).$$

(69)

By some standard argument, we can get, as $n \to \infty$,

1) $P(E_1) \to 0$ if

$$R_0 \geq I(X_1, X_2, \cdots, X_N; W) + \epsilon,$$

(70)

2) $P(E_2|E_1^c) \to 0$, 

3) $P(E_3|E_1^c, E_2^c) \to 0$ if for each $i = 1, 2, \cdots, N$,

$$R_i \geq H(X_i|W) + \epsilon.$$

(71)

This completes the achievability proof.

For the converse part, we want to show that for any
achievable rate tuple $(R_0, R_1, \cdots, R_N)$, it should satisfy (67)
and (68).

By Fano’s inequality, we have

$$H(X_i^n|M_1M_0) \leq n\epsilon.$$ 

(72)

Hence, we have, for $i = 1, 2, \cdots, N$

$$nR_i \geq H(M_i),$$

(73)

$$nR_i \geq H(M_i|0),$$

(74)

$$nR_i \geq H(M_i|0) + H(X_i^n|M_iM_0) - n\epsilon,$$

(75)

$$H(X_i^n|M_i|0) - n\epsilon,$$

(76)

$$H(X_i^n|0) - n\epsilon,$$

(77)

$$\sum_{j=1}^n H(X_{ij}|M_0X_i^{j-1}) - n\epsilon,$$

(78)

$$\sum_{j=1}^n H(X_{ij}|M_0, X_1^{j-1}, X_2^{j-1}, \cdots, X_N^{j-1}) - n\epsilon.$$ 

(79)

and

$$nR_0 \geq H(M_0),$$

(80)

$$nR_0 \geq I(M_0; X_1^n, X_2^n, \cdots, X_N^n),$$

(81)

$$= \sum_{j=1}^n I(M_0; X_{1j}X_{2j} \cdots X_{Nj}|X_1^{j-1}X_2^{j-1}\cdots X_N^{j-1})$$

(82)

$$= \sum_{j=1}^n I(M_0X_1^{j-1}X_2^{j-1}\cdots X_N^{j-1}; X_{1j}X_{2j} \cdots X_{Nj}).$$

(83)

Define $W_j = (M_0, X_1^{j-1}, X_2^{j-1}, \cdots, X_N^{j-1})$, and using
a standard time sharing argument, we can get, for $i = 1, 2, \cdots, N$,

$$R_i \geq H(X_i|W) - \epsilon,$$

(84)

$$R_0 \geq I(X_1X_2 \cdots X_N; W).$$

(85)

Let $n \to \infty$, then $\epsilon \to 0$, and this completes the proof
of converse. The cardinality bound can be obtained using
the technique introduced in [16, Appendix C]. We skip the
details. This completes the proof of Theorem 4. \qed

Now we proceed to prove Theorem 3. We will show that if
$R_0 > C(X_1, X_2, \cdots, X_N)$, it is achievable for Model I.
Let $R_0 > C(X_1, X_2, \cdots, X_N)$ and any $\epsilon > 0$ be given and
let random variables $(X_1, X_2, \cdots, X_N)$ satisfy (7) and (8),
such that

$$C(X_1, X_2, \cdots, X_N) = I(X_1X_2 \cdots X_N; W).$$

(86)

Notice that, the existence of such random variables is guaran-
teed by Lemma 3. Now define

$$\epsilon_1 = \min\{\frac{\epsilon}{N+1}, R_0 - C(X_1, X_2, \cdots, X_N)\},$$

(87)

and hence $\epsilon_1 > 0$. By Theorem 4, there exists a
$(n, M_0, M_1, \cdots, M_N)$ code with $P_e^{(n)} \leq \epsilon'$ and $\epsilon' \leq \epsilon_1$. 

Hence,

$$\frac{1}{n} \log M_0 \leq C(X_1, X_2, \cdots, X_N) + \epsilon_1 \leq R_0,$$ 

(88)

$$\frac{1}{n} \log M_i \leq H(X_i|W) + \epsilon_1.$$

(89)
Hence, we have,
\[
\sum_{i=0}^{N} \frac{1}{n} \log M_i \leq C(X_1, X_2, \cdots, X_N) + \sum_{i=1}^{N} H(X_i | W) + \epsilon, \quad (90)
\]
where (a) is from condition (8). Thus, condition (14) is also satisfied. This implies that \(R_0\) is achievable in Model I, which completes the proof of achievability part. This completes the proof of Theorem 3. \(\square\)

B. Proof of \(C_2 = C_{X_1, X_2, \cdots, X_N}\).

In this section, we prove the second part of theorem 1, that is \(C_2 = C(X_1, X_2, \cdots, X_N)\). We have the following theorem.

**Theorem 5:**

\[
C_2 \geq C(X_1, X_2, \cdots, X_N), \quad (92)
\]
\[
C_2 \leq C(X_1, X_2, \cdots, X_N). \quad (93)
\]

For the converse part, that is (92), the proof follows almost the same line as in [4, Section 5.2]. For the achievability part, that is (93), the proof follows similarly as in [4, Section 6.2] by applying \(U = X_1 \times X_2, \cdots \times X_N\) in [4, Theorem 6.3]. We omit the details here.
